

**IDENTIFICATION AND CHARACTERIZATION OF A STEM
CELL-LIKE POPULATION IN OVARIAN CANCER**

by
Allison Catherine Sharrow

January, 2014

ABSTRACT

Eighty percent of patients with advanced ovarian cancer show an initial clinical response to therapy, but seventy-five percent of these patients eventually relapse. This transient clinical response would be consistent with the cancer stem cell hypothesis. A substantial body of recent evidence supports the cancer stem cell hypothesis in ovarian cancer. However, controversy exists regarding the phenotype of ovarian cancer stem cells. Additionally, their clinical relevance remains unclear.

In order to test the hypothesis that ovarian cancer contains a population of stem-like cells, aldehyde dehydrogenase 1 high (ALDH^{high}) cells from two ovarian cancer cell lines with distinct subtypes were examined for cancer stem cell properties. Compared to ALDH^{low} cells, ALDH^{high} cells displayed nonadherent growth, an absence of contact inhibition, smaller size, quiescence, the ability to regenerate the phenotypic diversity of the cell line, *in vivo* tumorigenicity, multi-drug resistance, and gene expression differences consistent with a stem cell phenotype. Because ALDH^{high} cells phenotypically resemble cancer stem cells, studying this population in two different subtypes may reveal biological properties of ovarian cancer stem cells. Differential gene expression suggested that the ALDH^{high} population had increased tight junction signaling, downregulation of tumor suppressors, increased invasion, and decreased coagulation. No consistent differences were observed in previously reported ovarian cancer stem cell markers, hormone receptors, Her-2/neu, CA125 or developmental pathways. The only ABC transporter with consistent upregulation was

MDR1. The ultimate goal of studying ovarian cancer stem cells is to develop therapies to eradicate these cells. Gene expression patterns in ALDH^{high} cells identified four potential therapeutic targets: mTOR, Her-2/neu, CD47 and FGF18.

This project provides further support for the existence of ovarian cancer stem cells as well as the use of high aldehyde dehydrogenase 1 activity for their isolation. Few studies have comprehensively examined ovarian cancer stem cells from multiple subtypes. This work demonstrated substantial variability between the two studied subtypes. However, those features that were consistent would likely represent universal features of ovarian cancer stem cells. Finally, the potential therapeutic targets identified in this study may allow patients with ovarian cancer to achieve durable remission.

ACKNOWLEDGEMENTS

Throughout the course of my graduate career, I was blessed to have the support and guidance of my thesis committee members: Richard Jones, Edward Gabrielson, Deborah Armstrong, Richard Roden and David Berman. The project was fraught with technical difficulties and I never felt reproached by any of you. Instead, I could always count on your understanding and encouragement, for which I am greatly appreciative. I was also fortunate to have a thesis mentor, Richard Jones, who allowed me to develop as an independent researcher. You provided guidance when I needed it and independence when I was ready for it. I have learned a great deal about how to approach a project and the difficulties that come with it. I appreciate that you never chastised me for those difficulties or my mistakes but rather helped me to overcome them.

During my rotation in the Jones lab, I felt like I stepped into a family. I am glad to have been welcomed into that family. Each of you has helped me in different ways and has made my thesis work very enjoyable. Although faces have changed over time, I thank all of you for your help and camaraderie: Jamie Barber, Milada Vala, Brandy Perkins, Margaret Showel, Jon Gerber, Gabriel Ghiaur, Sarah Morse, Meng Su, Salvador Alonso, Bree Yanagisawa, Heather Johnson, Tina Bauer, Tenera Coates, and honorable member of the lab Qiuju Wang.

I am also grateful for the many collaborators that assisted me over the course of my graduate career. Michael Collector, thank you for putting up with my animals

and me for so many years. I could not have done it without you. Also, thank you for all of the cooking tips. I am indebted to Allan Hess and Chris Thoburn for providing me with the FNAR model and the knowledge I needed to handle the cells. I also need to thank Ie-Ming Shih, Tian-Li Wang and Alex Stoeck for providing me with the taxol-resistant SKOV3 subline. Dr. Shih, I also appreciate your input and guidance over the years. You helped me to overcome the difficulty of being the only person studying ovarian cancer in a hematological malignancies lab. Wayne Yu, thank you for all of your guidance on the microarray and PCR validation experiments. Brian Simons, thank you for helping with the animals and the tumor validation.

I am fortunate to have been a member of the Pathobiology program. My classmates made my first year as close to fun as classes would allow. Several of you have become dear friends over the years. I appreciate that the faculty and administration have always been available to lend support and guidance. I especially need to thank Noel Rose and our fabulous program coordinators: Wilhelmena Braswell, Nancy Nath and Tracie McElroy.

Several people helped shape the course of my early career and influenced my path to Johns Hopkins. James Pipas offered me my first research position, which led me to pursue a career in academic research. In the Pipas Lab, Paul Cantalupo and Sean Hasso introduced me to lab techniques and taught me how to design experiments. Thank you for laying the groundwork of my career. Harry Blair allowed me to expand my experience with a research associate position after graduation. The

time I spent in the Blair Lab confirmed that I had chosen the correct field. I was also fortunate to find a mentor, not just a boss. You encouraged me to continue with my education and believed in my ability to excel at an Ivy League institution. Thank you for continuing to mentor me long after I have left your lab. It gives me confidence to know that I always have you in my corner.

I must thank my friends and family for their continued support throughout my education. My friends in Baltimore and elsewhere helped to remind me to have fun in graduate school and accepted my absence when classes and lab work dominated my time. I am eternally grateful for your friendship. I will always feel blessed for my loving and supportive family. I do not know what I did in a past life to deserve all of you, but I am thankful that I have you. My parents, Paul and Janice Sharrow, have shaped me into the person I am today. Thank you for always believing in me and always being there for me. Thank you to my siblings, Ian and Molly Sharrow, for keeping me grounded and making sure that I never take myself too seriously. Thank you to my grandparents, Larry and Doris Foster and Harriet Sharrow, for your loving support. Finally, I need to thank my husband, Leo Ziegler. You have been my rock throughout graduate school. When I questioned myself, you reassured me. I could not imagine doing this without you. Thank you for putting up with me in graduate school. Hopefully, it gets easier now; but if not, I know we can handle anything together.

Introduction

Cancer Stem Cell Hypothesis

Current cancer treatments primarily employ three strategies: surgery, radiation and chemotherapy. Each of these approaches has a long history of clinical use. Surgical resection was first documented in 1500 B.C¹. Radiation therapy for the treatment of cancers not able to be surgically removed was introduced in 1902². Chemotherapy began in the middle of the 19th-century with the use of arsenic³. However, the basis for modern chemotherapy arose from nitrogen mustard after World War II⁴. Despite significant refinements to these strategies since their inception,

cancer persists as the second leading cause of death in the United States with 38% of cancer patients succumbing to their disease⁵.

It is becoming increasingly apparent that simply refining current treatment approaches will not substantially impact patient outcomes, and novel approaches are necessary. Many patients show an initial clinical response to standard therapy, often achieving complete remission. However, a significant percentage of patients eventually relapse. The cancer stem cell hypothesis may explain this pattern of transient clinical response. This model proposes that cancer exhibits a similar hierarchy as normal tissues in that a small subset of primitive cells (cancer stem cells) produces the differentiated progeny that constitute the tumor bulk. The hypothesis further suggests that cancer stem cells persist after standard chemotherapy and initiate relapse. If this cell population could be specifically targeted for treatment, perhaps durable remission could be achieved.

Accepted properties of tissue stem cells provide theoretical support for the cancer stem cell hypothesis. Tissue stem cells typically survive longer than differentiated cells, providing sufficient time to accumulate the multiple genetic alterations necessary for malignancy⁶. Additionally, differentiated cells typically undergo only a limited number of cell divisions. In order to produce the large numbers of cells present in a tumor, significant cellular reprogramming of differentiated cells would be required to increase their proliferative potential. In

contrast, stem cells possess a substantially greater capacity for cell division, requiring fewer alterations to produce a malignant mass.

Although theoretically supported, insufficient evidence existed to confirm the cancer stem cell hypothesis. The stochastic model serves as an alternative explanation for treatment resistance. This model proposes that chemoresistance may develop in a random sampling of the initial population, and any cell remaining after treatment is potentially tumorigenic. The stochastic and cancer stem cell models present opposing explanations of cancer with profound implications for research. Research into the development of treatment strategies based on the stochastic model attempt to overcome first-order kinetic resistance with approaches such as increasing dose-intensity. In contrast, approaching cancer from the perspective of the cancer stem cell hypothesis requires identification of the tumorigenic population and the design of treatments to specifically eradicate this subset of cells. Until relatively recently, cancer researchers primarily accepted the assumptions of the stochastic model. Gradually, though, evidence accumulated in support of the cancer stem cell hypothesis, forcing some to reconsider their approach to cancer research.

Early Evidence of Cancer Stem Cells

The earliest evidence for the existence of cancer stem cells dates to the 1950's. Observations of chromosome numbers indicated that only a subset of cancer cells possessed the capacity for cell division⁷. Further analysis of chromosome patterns led to the proposal that this population was responsible for metastasis⁸. In the 1960's and

1970's, injections of tritiated thymidine permitted *in vivo* monitoring of cell division in leukemia cells. Initial results showed that cell division was restricted to the bone marrow, which houses hematopoietic stem cells⁹. Subsequent analysis revealed the existence of a quiescent leukemic population capable of reentering the cell cycle¹⁰. Thus, research spanning 25 years established heterogeneity in the capacity for proliferation within cancer. Additionally, these findings suggested that chemotherapies based on rapid proliferation would not eliminate the quiescent population¹⁰.

Although results to this point were suggestive, the technology available at that time could not distinguish between the stochastic and cancer stem cell models. To support the cancer stem cell hypothesis, a tumorigenic population needed to demonstrate a stem cell-like phenotype distinct from the nontumorigenic cells. Additionally, it was essential that this tumorigenic population produce nontumorigenic cells. Conversely, the nontumorigenic population could not produce tumorigenic cells, consistent with the accepted unidirectional nature of differentiation. Recent advancements in technology permitted evaluation of these features. The introduction of cell sorters in the 1970's permitted isolation of individual cells from a heterogeneous sample. Initially though, cells could only be resolved based on size, DNA content or protein content. The ability to produce protein-specific antibodies in 1975 revolutionized cell sorting¹¹. Cells could then be distinguished based on expression of particular proteins. The final necessary advancement was the ability to

reliably expand human cells *in vivo* using xenografts. With these technologies in place, cells could then be isolated based on protein expression, expanded in immunocompromised mice, and the resulting cells could be examined. Using this methodology, the specific cellular components of hematopoiesis were identified based on cell surface protein expression.

The first support to arise from these technological advancements was the identification of a subset of leukemia cells that shared cell surface markers with normal stem and progenitor cells¹². These results indicated a differentiation hierarchy in cancer and implied a stem cell origin for cancer. What many considered to be definitive evidence was presented in 1994 when Lapidot et. al. demonstrated that tumorigenicity was restricted to the small subset of leukemia cells that shared cell surface expression patterns with normal hematopoietic stem cells¹³. With this data, a primary feature of the stochastic model was challenged. Every cell within the cancer did not possess the same tumorigenic capacity. Furthermore, the tumorigenic population displayed a stem cell phenotype.

Modern Evidence of Cancer Stem Cells in Hematological Malignancies

The first two cancers in which cancer stem cells were identified were acute myeloid leukemia (AML) and chronic myelogenous leukemia (CML). Initial reports indicated that the AML stem cell shared cell surface marker expression with normal hematopoietic stem cells ($CD34^+CD38^-$), although recent reports have challenged this phenotype¹³⁻¹⁵. This controversy may be due to reliance on engraftment into

immunocompromised mice as the primary assay of tumorigenicity. Recently, persistence of CD34⁺CD38⁻ AML stem cells has been shown to predict relapse in patients¹⁶. This provided the first evidence for the clinical relevance of cancer stem cells. This further showed that clinical correlations might more accurately identify tumorigenic populations than xenograft models. As in AML, the CML stem cell shares a phenotype with normal hematopoietic stem cells (CD34⁺CD71⁻)¹⁷. Additional characterization of the CML stem cell reported high aldehyde dehydrogenase activity¹⁸.

Multiple myeloma has generally been considered to be a disease of plasma cells. Clonotypic plasma cells expand in the marrow, producing elevated levels of monoclonal antibodies in the blood. The multiple myeloma stem cell has been shown to phenotypically resemble a memory B cell, which differentiates into malignant plasma cells¹⁹. Subsequent analysis demonstrated that these clonotypic B cells are resistant to chemotherapy drugs used clinically to treat the disease²⁰. Although multiple myeloma research lags behind that of leukemia, preclinical testing of a multiple myeloma stem cell-targeted therapy reported promising results. Multiple myeloma stem cells overexpress HLA class I, and an HLA class I-crosslinking antibody induced cytotoxicity²¹. Further testing should determine the clinical effectiveness of this treatment approach.

Similar to multiple myeloma, the prominent cells in Hodgkin lymphoma do not appear to drive the disease. In addition to the disease-defining Reed-Sternberg cells,

Hodgkin lymphoma contains a population of clonotypic memory B cells²². These cells generate Reed-Sternberg cells *in vitro* and likely represent the initiating cell in Hodgkin lymphoma²². Characterization of these cells also showed high aldehyde dehydrogenase activity²².

Cancer Stem Cells in Solid Tumors

Knowledge of the normal differentiation hierarchy in hematopoiesis facilitated the identification of cancer stem cells in hematological malignancies. In addition to characterizing markers of each stage of hematopoiesis, this early work developed purification techniques as well as *in vivo* and *in vitro* functional assays. In contrast, identification of cancer stem cells in solid tumors is hampered by a lack of understanding of their normal counterparts. Markers of primitive cells must be empirically determined, which causes much controversy. Because of these difficulties, the first cancer stem cell in a solid tumor was not described until 2003 with the identification of tumorigenic breast cancer cells²³. This work required evaluation of a variety of cell surface proteins in order to identify those with heterogeneous expression. Cells with high and low levels of expression were then compared for tumorigenicity in order to identify breast cancer stem cell markers. Since this early work, cancer stem cells have been reported in many types of solid tumors, including ovarian cancer.

Ovarian Cancer Stem Cells

Eighty percent of patients with advanced ovarian cancer show an initial clinical response to therapy, but seventy-five percent of these patients eventually relapse²⁴. This transient clinical response would be consistent with the cancer stem cell hypothesis. The initial response could be attributed to the eradication of the bulk, differentiated cells. The persistence of drug resistant cancer stem cells could be responsible for the almost invariable relapse. Therefore, if the cancer stem cell hypothesis is accurate, ovarian cancer will likely contain a population of stem-like cells. A substantial body of recent evidence supports the cancer stem cell hypothesis in ovarian cancer. However, controversy exists regarding the phenotype of ovarian cancer stem cells. Additionally, their clinical relevance remains unclear.

In 2005, the first evidence for ovarian cancer stem cells described the enrichment of tumorigenic cells from patient samples using non-adherent culture²⁵. This initial report initiated a body of research by describing the tumorigenic cells as CD44⁺²⁵. Several groups isolated CD44⁺ ovarian cancer cells and reported the stem cell features of tumorigenicity, chemoresistance and expression of stem cell factors²⁵⁻³¹. Clinical evaluation showed that a high percentage of CD44⁺ cells correlates to shorter progression-free survival, but not overall survival^{32, 33}. However, conflicting data challenges the use of CD44 as an ovarian cancer stem cell marker. Comparisons of tumorigenic and nontumorigenic ovarian cancer cells reported no difference in CD44 or reduced CD44 expression in the tumorigenic cells³⁴⁻³⁷. Furthermore, CD44⁻

cells generated CD44⁺ cells, which violates unidirectional differentiation if CD44 expression identifies ovarian cancer stem cells³⁰.

The second report of ovarian cancer stem cells employed side population for enrichment³⁴. The side population phenotype is presumed to be the results of Hoechst 33342 dye extrusion due to increased expression of drug transporters, especially ABCG2^{38, 39}. Ovarian cancer cells isolated based on the side population phenotype displayed the stem cell features of tumorigenicity, quiescence, chemoresistance and expression of stem cell genes^{27, 34-36, 40-43}. Additionally, others reported increased expression of ABCG2 in their putative ovarian cancer stem cell population^{29, 35, 44}. Clinically, relapsed patients demonstrated a higher percentage of side population cells compared to patients with primary, chemonaïve disease⁴¹. Although many reports support the use of side population as an ovarian cancer stem cell marker, conflicting reports also challenge this assertion. A survey of clinical samples only detected side population cells in one third of patients⁴⁵. If side population enriches for ovarian cancer stem cells, all patients should possess this population. Although expression of ABCG2 is believed to cause the side population phenotype, expression of ABCG2 does not correlate with tumorigenicity^{40, 46}. Finally, Hoechst 33342 dye induces cytotoxicity, causes DNA mutations and disrupts the cell cycle⁴⁷. Because side population cells more efficiently remove the dye, their apparent increased tumorigenicity may in fact be due to the cytotoxic effects of the dye on non-side population cells.

The use of CD133 expression as an ovarian cancer stem cell marker began with the observation that CD133⁺ primary tumor cells produce more cells than CD133⁻ cells⁴⁸. Subsequent work demonstrated multiple stem cell features in CD133⁺ cells, including tumorigenicity, drug resistance, the ability to generate CD133⁻ cells, and increased expression of stem cell genes^{44, 49-53}. Evaluation of clinical specimens showed an increase in the percentage of CD133⁺ cells in relapse tumors compared to primary tumors⁵⁴. Furthermore, patients with CD133⁺ cells showed a slightly poorer progression-free and overall survival than patients without CD133⁺ cells⁵⁵. However, for every stem cell feature reported in CD133⁺ cells, conflicting data exists. Only 30-70% of patients possess any CD133⁺ tumor cells^{55, 56}. As with the side population phenotype, all patients should possess ovarian cancer stem cells. Furthermore, CD133 expression does not correlate with tumorigenicity^{34, 46}. Both CD133⁺ and CD133⁻ cells produce tumors with heterogeneous CD133 expression, which would not occur if CD133 expression decreases with differentiation⁵⁰. Finally, the percentage of CD133⁺ cells in a patient's tumor provides no prognostic value^{57, 58}.

More recently, CD24 expression has been proposed to enrich for ovarian cancer stem cells. CD24⁺ cells exhibited the stem cell features of tumorigenicity, chemoresistance, the ability to produce CD24⁻ cells, and expression of stem cell genes^{35, 59, 60}. However, a conflicting report showed stem cell features in CD24⁻ cells instead⁴⁶. While tumorigenic cells differentially express CD24, the direction of this difference varies³⁴.

Early reports of ovarian cancer stem cells indicated higher levels of KIT (CD117) expression, yet very few studies exclusively studied KIT. The one study that specifically compared KIT⁺ to KIT⁻ cells demonstrated tumorigenicity in the KIT⁺ population⁶¹. They additionally established a correlation between patients with detectable KIT⁺ cells and chemoresistance⁶¹. The only other evidence for KIT as an ovarian cancer stem cell markers depends on measuring KIT expression in tumorigenic ovarian cancer cells isolated by other means. While some studies found increased KIT expression in tumorigenic cells, other studies detected the same or lower levels of KIT^{25, 29, 34, 35, 44, 52}. Furthermore, only 40-45% of tumor samples contain any KIT⁺ cells^{56, 61}.

The numerous reports of high aldehyde dehydrogenase 1 activity (ALDH^{high}) in normal and malignant stem cells have led some to propose that ALDH^{high} ovarian cancer cells represent ovarian cancer stem cells⁶²⁻⁶⁸. ALDH^{high} ovarian cancer cells display tumorigenicity, the ability to generate ALDH^{low} cells, and chemoresistance^{51, 56, 69-73}. Clinically, higher percentages of ALDH^{high} cells correlate to poorer progression-free and overall survival^{56, 69-71}. However, one study showed an improved prognosis with higher percentages of ALDH^{high} cells⁷⁴. In addition to this conflicting report, other inconsistencies exist. One study could not detect ALDH^{high} cells in 23.1% of 65 ovarian cancer samples, however other studies detected ALDH^{high} cells in all 18 and 25 samples tested^{51, 56, 69}. Finally, some reports detected ALDH^{high} cells in xenografts from ALDH^{low} cells^{51, 71}.

The preponderance of evidence supports the existence of ovarian cancer stem cells. However, uncertainty remains surrounding the ideal marker for their isolation. For each proposed marker, reports exist both in support and opposition, and very few studies compare multiple markers. One study measured expression of CD44, CD133, CD24, KIT and ALDH1 in 13 primary tumors and five ascites samples. The only marker with limited expression in all samples was ALDH1⁵⁶. Another study examined CD44 and ALDH1 expression in tumorigenic cells. Despite stable CD44 expression, the loss of ALDH1 activity correlated with reduced tumorigenicity³⁰. These two studies support the use of ALDH1 expression as a marker of ovarian cancer stem cells over other proposed markers. Finally, expression of CD133 may enrich for endothelial progenitor cells to support the growth of the tumor, rather than ovarian cancer stem cells⁷⁵. While this limited evidence begins to clarify the value of distinct ovarian cancer stem cell markers, further research is required.

Research Plan

I sought to test the hypothesis that ovarian cancer contains a population of stem-like cells. I selected two models of ovarian cancer for this study. The first is a rat model of ovarian cancer, termed FNAR-C1, that is described in detail in Chapter Two. Briefly, this spontaneously occurring ovarian tumor expands *in vivo* and forms tumors in immunocompetent rats. Histological evaluation determined that FNAR-C1 most closely resembles the endometrioid subtype. In order to control for potential subtype differences, the SKOV3 cell line was also utilized. The subtype of SKOV3

cells has been described as both clear cell and serous^{76, 77}. In addition to the parental SKOV3 line, I also employed a taxol-resistant SKOV3 subline.

Next, I determined the methodology for isolation of putative ovarian cancer stem cells. At the initiation of this project, only two reports described stem-like cells in ovarian cancer. The isolation methods used nonadherent growth and side population. Tumorigenic cells expressed variable levels of cancer stem cell markers previously reported for other cancers (KIT, CD44, CD24 and CD133). Based on these results, I selected a marker not examined in these studies. High aldehyde dehydrogenase 1 (ALDH1) activity has been reported in many normal and malignant stem cells⁶²⁻⁶⁸. The ALDH superfamily of enzymes oxidizes intracellular aldehydes. Specifically, the ALDH1 family converts vitamin A into retinoic acid. On this basis, I chose high ALDH1 activity as a putative marker of ovarian cancer stem cells. In order to isolate viable cells on the basis of enzyme activity, I used the Aldefluor reagent developed in the laboratory of my advisor⁷⁸. Aldefluor serves as a fluorescent substrate of ALDH1. BODIPY-acetaldehyde freely diffuses into cells, where ALDH1 converts it to BODIPY-retinoic acid. Once modified by ALDH1, Aldefluor can no longer exit the cell through passive diffusion. Fluorescence accumulates in cells with high ALDH1 activity, which can then be isolated with a cell sorter.

Once ovarian cancer cells were isolated based on ALDH1 activity, I tested the populations for cancer stem cell properties. On the basis of these tests, I confirmed that ALDH^{high} cells represent a less differentiated population in ovarian cancer than

ALDH^{low} cells. Next, I characterized expression differences between these populations to better understand the biology of ovarian cancer stem cells. Finally, expression patterns revealed potential therapeutic targets to more effectively treat ovarian cancer.

This project contributes to the understanding of ovarian cancer in several ways. First, FNAR-C1 cells provide a novel model for the study of ovarian cancer with advantages over current animal models. This model circumvents current controversy surrounding assessment of *in vivo* tumorigenicity in immunocompromised animals with its transplantability into immunocompetent rats. The cell line expands *in vitro*, allowing for more detailed analysis. Because the tumor arose spontaneously, it lacks artificial genetic manipulations that may not occur in the human disease. Overall, this model may serve as a valuable experimental model to improve understanding of the biology of ovarian cancer.

This project further supports the existence of ovarian cancer stem cells and the use of high aldehyde dehydrogenase activity as an ovarian cancer stem cell marker. Comparison of expression differences between stem and differentiated cells provides insight into the biological differences between these cell populations. Additionally, the use of models from two discrete ovarian cancer subtypes controls for potential subtype-specific differences. Since few studies compare the various proposed ovarian cancer stem cell markers, analyses included all previously reported markers. Finally, this project proposes potential therapeutic targets based on examination of expression

patterns, which has not yet been explored in detail. Thus, this project expands understanding of ovarian cancer stem cells with the purpose of designing targeted therapeutics.

Hypothesis

Ovarian cancer contains a population of cells with stem-like characteristics that is responsible for relapse.

Research Objectives:

1. Isolate and validate cancer stem cells in ovarian cancer
2. Characterize cancer stem cells in ovarian cancer
3. Identify potential therapeutic targets

2

Identification and characterization of a spontaneous ovarian carcinoma in Lewis rats.

Sharrow AC, Ronnett BM, Thoburn CJ, Barber JP, Giuntoli RL, Armstrong DK, Jones RJ, Hess AD.
J Ovarian Res. 2010 Mar 31; 3:9.

Background

Ovarian cancer is the fifth most commonly diagnosed cancer in women and the fourth most common cause of death from cancer⁷⁹. The high mortality can be attributed to the high percentage of affected women presenting at an advanced stage, with spread within the peritoneal cavity^{80, 81}. With current therapies, including surgical debulking and platinum-based chemotherapy, patients in stage III or stage IV only have a 20% chance of long-term survival^{80, 81}. Better understanding ovarian carcinoma biology, as well as the development of new therapies for the disease, has been hampered by the lack of suitable animal models.

Current ovarian cancer models fall into three broad categories: rare spontaneous carcinomas, induced tumors, and human xenografts⁸². Although these models have allowed researchers to gain valuable insights into the biology of ovarian cancer, each model exhibits important limitations^{82, 83}. Spontaneous ovarian cancer has been observed in mice, rats, and hens⁸⁴⁻⁸⁶. The drawback to these models is that the cancers tend to occur at an advanced age and at similar low frequencies as in humans. The low incidence and the length of time required for the development of these tumors render them of limited use for studying the biology and treatment of ovarian carcinoma. Induced tumor models circumvent these problems but create their own artificial systems, which may not accurately reflect the human disease. In one model of *in vitro* transformation, ovarian surface epithelium cells are subcloned until they exhibit the loss of contact inhibition, the capacity for substrate-independent growth, cytogenetic abnormalities, and the ability to form tumors when injected subcutaneously and/or intraperitoneally into athymic mice⁸⁷. This model, though, fails to account for critical interactions between the cancer cells and the host. Also, it is uncertain if these cells or their malignant transformation are representative of normal human cells or clinical disease.

Animal models have been generated by expressing simian virus 40 large T antigen⁸⁸, by inactivating p53 and Rb1⁸⁹, by inactivating p53 and activating an oncogene⁹⁰, and through hormone treatment⁹¹⁻⁹³. The high rate of cancer development in these animals makes these models attractive, but they may not reliably

represent human cancer because a majority of these genetic changes usually do not occur in patients. Xenografts of human cancers have undergone continuous improvement over the past twenty years⁹⁴⁻⁹⁷. These models allow for direct examination of the human cancer but do not allow the study of the early stages of the cancer. These models also rely on an immune-deficient host, which eliminates the interaction between the cancer and the immune system.

We present a new model of ovarian carcinoma, designated FNAR, that spontaneously developed in an untreated, previously normal Lewis rat. The tumor could be serially passaged both *in vivo* as malignant ascites in rats and *in vitro*. Importantly, the biologic characteristics of the tumor closely paralleled one type of human ovarian carcinoma.

Methods

Animals. Female Lewis strain rats aged 4-6 weeks (purchased from Charles River Breeding Laboratories, Inc., Wilmington, MA) were kept in sterile micro-isolator cages and fed food and water *ad libitum*. The institutional guidelines of Johns Hopkins University concerning the care and use of research animals were followed. The animals were challenged intraperitoneally with graded numbers of FNAR cells and monitored daily for abdominal swelling. At various intervals after tumor challenge or when animals appeared moribund (pallor, lethargy, and marked abdominal distension), the animals were sacrificed by CO₂ asphyxiation and the cells within the peritoneal cavity harvested by flushing the abdomen with 35 milliliters of

sterile phosphate buffered saline (PBS, Grand Island Biological Co., Gibco BRL, Grand Island, NY). At sacrifice, the animals were examined for tumor growth and tissues taken for histological examination.

In vitro propagation and growth curve. A cell line (FNAR) that grows *in vitro* as an adherent monolayer was established by culture in RPMI 1640 (Gibco) supplemented with 10% fetal calf serum in 30 ml tissue culture flasks (Corning Flask 3056, Corning Inc., Corning NY). Cells used for experiments were low passage and maintained in culture for one to three months. The doubling time of the cell line was measured by plating 10^4 cells into microtiter wells then harvesting and counting at 19.5, 43.5, and 115.5 hours.

Flow Cytometric Analysis. Flow cytometry was utilized to assess *in vitro* FNAR cells for expression of known phenotypic markers. Briefly, 5×10^5 tumor cells were incubated in polystyrene tubes. Analysis of the intracellular antigens estrogen receptor α , progesterone receptor, and androgen receptor first required fixation in 2% formaldehyde (Polysciences, Warrington, PA) in phosphate buffered saline (PBS, Gibco Invitrogen, Carlsbad, CA) for 15 minutes at 4°C followed by permeabilization with 0.1% Triton-X-100 (Sigma-Aldrich, St. Louis, MO) in PBS for 15 minutes at 4°C. The cells were then incubated for 30 minutes at 4°C with commercially purchased murine monoclonal antibodies. The concentrations of antibodies used are as follows: estrogen receptor (ER) α at $8 \mu\text{g}/10^6$ cells (Abcam, Cambridge, MA), progesterone receptor (PR) at $16 \mu\text{g}/10^6$ cells (Affinity Bioreagents, Golden, CO), or

androgen receptor (AR) at 2 $\mu\text{g}/10^6$ cells (Pharmingen, San Diego, CA). The cells were washed and counterstained with phycoerythrin (PE) rat anti-mouse IgG₁ (Becton Dickinson, San Jose, CA) at 125 ng/ 10^6 cells for 30 minutes at 4°C. Commercially purchased murine monoclonal antibody to the rat c-neu oncogene product (Calbiochem, San Diego, CA) was used at 1 $\mu\text{g}/10^6$ cells and was counterstained with PE rat anti-mouse IgG_{2a+b} (Becton Dickinson, San Jose, CA) at 30 ng/ 10^6 cells for 30 minutes at 4°C. Tumor cells incubated with secondary antibody alone served as a negative control. Epithelial cell adhesion molecule (EPCAM) expression was analyzed using a PE-conjugated antibody (Santa Cruz, Santa Cruz, CA) at 1 $\mu\text{g}/10^6$ cells with mouse IgG₁-PE as a negative control (Becton Dickinson, San Jose, CA). A commercially available rabbit polyclonal antibody to CA125 (Abbiotec, San Diego, CA) was used at 2 $\mu\text{g}/10^6$ cells and counterstained with 1 $\mu\text{g}/10^6$ cells APC goat anti-rabbit IgG (Invitrogen Molecular Probes, Carlsbad, CA). The cells were analyzed on a Becton-Dickinson FACSCalibur flow cytometer and data was analyzed using FlowJo (Tree Star, Inc, Ashland, OR).

Immunocytochemistry. FNAR cells were plated onto four-well CultureSlides (BD Falcon, San Jose, CA). Cells were fixed in 2% formaldehyde in PBS for 20 minutes followed by permeabilization in 0.5% Triton X-100 in PBS for 10 minutes. Cells were then incubated with a mouse monoclonal antibody to beta-catenin conjugated to Cy3 (Abcam, Cambridge, MA) at 6 $\mu\text{g}/\text{ml}$ for one hour and counterstained with 500 ng/ml DAPI for five minutes (Invitrogen Molecular Probes,

Carlsbad, CA). Images were captured using the Nikon Eclipse E800 (Tokyo, Japan) at 200x magnification with standard filters for DAPI and Cy3, the DS-QiMc digital camera (Nikon, Tokyo, Japan), and the Advanced Research Elements AR 3.0 software (Nikon, Tokyo, Japan).

Gene Expression Analysis by cDNA Microarrays. RNA was extracted and purified from cell lysates of $1-5 \times 10^5$ *in vitro* FNAR tumor cells and the REH cell line of normal rat endothelial cells, as a control, with 500 μ l Trizol reagent (Invitrogen, Carlsbad, CA). Tissue samples were frozen in liquid nitrogen and pulverized with a mortar and pestle. The powder was dissolved in Trizol and centrifuged. Purified RNA was dissolved in 20 μ l diethyl-pyrocabonate-treated distilled water. The resulting RNA was analyzed at the Johns Hopkins microarray core. RNA from control and experimental samples was processed using the RNA amplification protocol described by Affymetrix (Affymetrix Expression Manual). Briefly, 5 μ g of total RNA was used to synthesize first strand cDNA using the SuperScript Choice System (Invitrogen, Carlsbad, California) and oligonucleotide primers with 24 oligo-dT plus the T7 promoter (Proligo LLC, Boulder, Colorado). Following the double stranded cDNA synthesis, the product was purified by phenol-chloroform extraction and biotinylated anti-sense cRNA was generated through *in vitro* transcription using the BioArray RNA High Yield Transcript Labeling Kit (ENZO Life Sciences Inc., Farmingdale, New York). Fifteen μ g of the biotinylated cRNA was fragmented at 94°C for 35 minutes in buffer (100mM Tris-acetate, pH 8.2, 500mM potassium

acetate, and 150mM magnesium acetate), and 10µg of total fragmented cRNA was hybridized to the Affymetrix GeneChip rat 230 2.0 array (Santa Clara, CA) for 16 hours at 45°C with constant rotation (60 rpm). Affymetrix Fluidics Station 450 was then used to wash and stain the chips with a streptavidin-phycoerythrin conjugate. The staining was then amplified as follows: blocking was performed using goat IgG, then a biotinylated anti-streptavidin antibody (goat) was bound to the initial staining, and amplification was completed by the addition of a streptavidin-phycoerythrin conjugate. Fluorescence was detected using the Affymetrix 3000 7G GeneArray Scanner and image analysis of each GeneChip was done through the GeneChip Operating System 1.4.0 (GCOS) software from Affymetrix using the standard default settings. For comparison between different chips, global scaling was used to scale all probesets to a user defined target intensity (TGT) of 150.

Quantitative RT-PCR for Cytokine Expression. Quantitative RT-PCR (Taqman, Applied Biosystems, ABI, Foster City, CA) was utilized to assess levels of cytokine mRNA transcripts of *in vitro* FNAR cells as previously described⁹⁸. The oligonucleotide primers and fluoresceinated probes for the cytokine genes (IL-6, IL-12, and IL-18), ER, PR, and stathmin were purchased from ABI. Data were analyzed in real-time with Sequencer Detection version 1.6 software, with the results normalized against mRNA transcripts for the housekeeping gene glyceraldehyde-3-phosphate dehydrogenase (GADPH).

Results

Description of proband. Examination of a normal female Lewis rat sacrificed for harvesting normal splenic T cells showed a spontaneously occurring tumor (approximately 0.5 cm³) derived from the left ovary and attached to and invading the abdominal wall (Figure 2.1A). In addition, tumor studding was observed at several sites on the wall of the peritoneum, and ascites was present. Histologic evaluation revealed an epithelial neoplasm with features most consistent with an adenocarcinoma (Figure 2.1B). The tumor was composed of nests displaying admixed cribriform and solid architecture. The tumor cells had modest amounts of amphophilic/eosinophilic cytoplasm and relatively uniform, moderately atypical oval nuclei that were predominantly vesicular to modestly hyperchromatic with small nucleoli. Occasional mitotic figures and apoptotic bodies were noted, as was focal necrosis. Based on analogy to human ovarian epithelial tumors, this tumor most closely resembled a moderately differentiated endometrioid carcinoma (a cribriform variant of that subtype, with cells being less columnar than the classical human endometrioid carcinoma), with disease distribution paralleling a typical high-stage (human FIGO stage IIIB) ovarian carcinoma. Lymphocyte infiltration into the tumor mass was minimal at best, although numerous lymphocytes were present in the peritoneal fluid. The tumor was excised and pushed through a 100 micron wire mesh screen to obtain a single cell suspension.

Figure 2.1: Gross and Histologic Examination of Proband

Intraperitoneal tumor arising spontaneously in a Lewis rat has pathologic appearance of an ovarian adenocarcinoma. (A) Proband shows tumor of the left ovary and intraperitoneal tumor studding. (B) Histology reveals an adenocarcinoma.

In vivo and in vitro growth characteristics. Normal Lewis rats were given either intraperitoneal (IP) or subcutaneous injection of graded numbers (5×10^4 , 1×10^5 , 5×10^5 , or 1×10^6) of tumor cells. The animals were monitored daily for overall general health as well as degree of abdominal extension. The tumor repeatedly failed to grow subcutaneously, even with the administration of systemic immunosuppression (Cyclosporine, 10 mg/kg/d) or passage into thymectomized animals. However, all rats became moribund at 150-160 days after IP injection with 5×10^5 or 1×10^6 cells (Table 2.1). Rats injected with 1×10^5 cells became moribund around 175 days. Rats receiving IP injections of 5×10^4 cells generally did not appear ill by 6 months, but

tumor cells were detected in the peritoneal cavity when sacrificed on day 175. Tumor growth recapitulated that seen in the initial rat with IP tumoral masses adhering to all of the visceral organs and the abdominal wall. Histologically, the tumors appeared to be of epithelial origin. Affected rats also showed enlargement of the ovaries and fallopian tubes, with a marked increase in vascularization. Successful serial passage was conducted by IP challenge with 1×10^5 tumor cells harvested by flushing of the peritoneal cavity.

Table 2.1: Survival After Intraperitoneal Injection of FNAR Cells

Survival Following Tumor Challenge		
No. of Cells Injected	No. of Animals	Survival – Days (No. of Animals)
5×10^4	N = 6	175 (6)
1×10^5	N = 8	150 (4) 155 (3), 160 (1)
5×10^5	N = 6	155 (2), 160 (4)
1×10^6	N = 6	150 (5), 152 (1)

The survival time of rats corresponds to the number of FNAR cells injected intraperitoneally. Animals were observed daily for general health and abdominal extension. The animals were sacrificed upon becoming moribund, which was characterized by extreme lethargy, paleness, and abdominal extension. The abdominal cavity was examined histologically for the presence of tumor cells in the peritoneal fluid and for tumor masses attached to the visceral organs and the abdominal wall.

The doubling time of the FNAR cell line was measured by plating 10^4 cells into microtiter wells then harvesting and counting at 19.5, 43.5, and 115.5 hours (Figure 2.2). The slope of the line of log number of tumor cells versus hours estimates a doubling time of 22.9 hours.

Figure 2.2: *In Vitro* Growth Characteristics

In vitro doubling time was measured by plating 10^4 cells into large flat bottom microtiter wells. At the designated intervals, cells were harvested and counted. Data is presented as log number of tumor cells versus growth time. The slope of the line represents an estimate of the doubling time.

Biological characterization of FNAR. ER is detected in 60-90% of ovarian carcinomas⁹⁹⁻¹⁰³, 25-50% express PR^{99, 101-104}, and 45% expressed both^{101, 103}. AR is expressed in 50-70% of ovarian carcinomas^{102, 104}. Accordingly, in the appropriate clinical and pathologic setting, sex hormone receptor expression is characteristic of ovarian carcinoma^{103, 105}. The tumor expressed ER, PR, and AR by flow cytometry (Figure 2.3A-C), with ER and PR confirmed by PCR (data not shown). The tumor also expressed her-2/neu (Figure 2.3D), which is expressed in 25-35% of ovarian carcinomas^{106, 107}. The epithelial origin of this carcinoma was confirmed by its expression of EPCAM (Figure 2.3E). Consistent with previous reports of endometrioid carcinoma, FNAR cells display cell-surface expression of CA125 (MUC16, data not shown)¹⁰⁸. FNAR cells also show nuclear staining of β -catenin (Figure 2.4), which is strongly associated with the endometrioid subtype¹⁰⁹.

Figure 2.3: FNAR Expression of ER, PR, AR, Her-2/neu, and EPCAM

Flow cytometric evaluation of FNAR cells for expression of (A) ER, (B) PR, (C) AR, (D) Her-2/neu, and (E) EPCAM. In all five graphs, isotypic control is shown with a solid line and the antibody of interest is shown with a shaded area.

Figure 2.4. FNAR Expression of β -catenin

FNAR cells were stained with (A) β -catenin and (B) DAPI. The third panel (C) shows an overlay of the two images.

Gene expression profiling demonstrated that FNAR gene expression was similar to that reported for human ovarian carcinoma (Table 2.2). Metallothioneins are generally not found at immunohistochemically detectable levels in normal cells, but their expression increases in ovarian carcinoma with increasing grade¹¹⁰⁻¹¹². Metallothionein I was overexpressed 11.38-fold in FNAR cells when compared to endothelial cells, and metallothionein II showed 3.56-fold increased expression.

Table 2.2: Gene Chip Analysis of FNAR

<u>Gene Expression Profiling of FNAR Cells</u>		
Gene Description	EST Accession #	Relative Expression
Metallothionein I	AW141679	11.38
Metallothionein II	AW916991	3.56
Thioredoxin	AW140607	3.07
Stathmin	BF281472	3.23
b-myb	RGIAC37	3.33

Gene chip analysis of FNAR shows similarities to human ovarian carcinoma. RNA was harvested from FNAR and REH endothelial cell lines and analyzed by GeneChip at a Johns Hopkins core facility. Data are presented as the relative expression of the gene in FNAR compared to expression in endothelial cells.

Thioredoxin expression correlates with cis-diaminedichloroplatinum resistance¹¹³ and is expressed in FNAR cells 3.07-fold higher than in endothelial cells. Stathmin regulates microtubules during the formation of the mitotic spindle and is not expressed at detectable levels in normal cells; however, high-level expression is generally seen in ovarian carcinoma¹¹⁴⁻¹¹⁶. Accordingly, stathmin expression was 3.23-fold higher in FNAR cells than in endothelial cells. This data was confirmed by PCR (data not

shown). A nuclear factor that it is involved in cell cycle progression, b-myb, is also highly expressed in both FNAR cells (3.33-fold) and human ovarian carcinoma ¹¹⁷.

High levels of interleukin-6 (IL-6), a proinflammatory cytokine and hematopoietic growth factor, are found in both normal ovarian epithelium and human ovarian carcinoma ^{118, 119}. Interleukin-18 (IL-18) is a proinflammatory cytokine that stimulates interferon- γ production. Ovarian carcinoma expresses IL-18, but it is predominantly the pro-IL-18 form ¹²⁰. Interleukin-12 (IL-12) is a cytokine that encourages a T_h1 immune response. IL-12 has been detected in ascites fluid and serum of ovarian cancer patients ¹²¹, although no reports have examined the expression of IL-12 by the ovarian carcinoma cells themselves. Expression of all three cytokines by FNAR cells was detected by real time RT-PCR (Figure 2.5).

Figure 2.5: FNAR Expression of IL-6, IL-12, and IL-18

Discussion

We present here a model of ovarian carcinoma, designated FNAR, that arose spontaneously in a normal Lewis rat. Importantly, FNAR's biology closely parallels the human disease. IP transplantation into rats produces malignant ascites and peritoneal carcinomatosis, leading to death at 5-6 months. The tumor only develops in the peritoneal cavity, suggesting the tumor microenvironment is intact during formation. Cells from the tumor can be easily passaged *in vitro*, and the cell line shows similar growth characteristics when returned to rats. Its morphology and expression of EPCAM are consistent with an epithelial carcinoma, and like human ovarian carcinoma, it expresses her-2/neu, sex hormone receptors, and characteristic cytokines. FNAR also displays a similar gene expression pattern to the human disease. Consistent with the endometrioid subtype, FNAR cells show cell-surface expression of CA125 and nuclear expression of β -catenin.

The FNAR model may address many of the limitation of current model systems for ovarian carcinoma. Rats transplanted with FNAR consistently become moribund by 5-6 months, avoiding the low frequency and long latency of spontaneous animal models. Xenografts of primary human tumors in immunodeficient mice are perhaps the most attractive current model⁹⁴⁻⁹⁷. Although spontaneous human cancers can be studied and used to test treatments in these mice, the study of immunotherapeutic approaches is problematic. Conversely, FNAR develops in immunocompetent rats, allowing the study of immunotherapeutic approaches. The

expression of all three sex hormone receptors and her-2/neu also allows for manipulations of these pathways using this model. However, the application of this model to the treatment of human disease remains to be established.

3

Materials and Methods

Cell Lines and Culture

FNAR-C1 rat ovarian cancer cells were obtained as previously described¹²². The human ovarian cancer cell line SKOV3 and taxol-resistant SKOV3 cells were the kind gifts of Drs. Alexander Stoeck, Tian-Li Wang and Ie-Ming Shih. Cells were maintained in two different media. The first was KnockOut medium, which is a proprietary serum-free medium designed for culturing embryonic stem cells in an undifferentiated state and consists of KnockOut DMEM (Life Technologies, Grand Island, NY) with 10% KnockOut Serum Replacement (Life Technologies, Grand Island, NY), 2 mM L-glutamine (Life Technologies, Grand Island, NY), 100 U/mL

penicillin (Life Technologies, Grand Island, NY) and 100 µg/mL streptomycin (Life Technologies, Grand Island, NY). Cells were also cultured in standard medium: RPMI (Life Technologies, Grand Island, NY) with 10% FBS (Sigma, St. Louis, MO), 2 mM L-glutamine, 100 U/mL penicillin and 100 µg/mL streptomycin. For reasons described in Chapter 4, standard medium will hereafter be referred to as differentiation medium. Taxol-resistant SKOV3 cells were continuously incubated with 33.3 nM paclitaxel (taxol; Sigma-Aldrich, St. Louis, MO). Cells were expanded in vented T175 tissue culture flasks.

Cell Sorting

For cell sorting, adherent cells were released from flasks with 0.05% trypsin-EDTA (Life Technologies, Grand Island, NY) and pipetting. Cells were stained with Aldefluor reagent (STEMCELL Technologies Inc., Vancouver, BC, Canada) using the manufacturer's protocol then stained with 0.5-1 µg/mL propidium iodide (Sigma-Aldrich, St. Louis, MO) for 5 minutes. FNAR-C1 cells grown in KnockOut medium were sorted using a MoFlo cell sorter (Beckman Coulter, Miami, FL). Because of substantial death after sorting, these cells were allowed to recover before use in the following experiments: doubling time, cell cycle analysis and drug resistance. No greater than 3×10^6 cells were plated in KnockOut medium in vented T175 tissue culture flasks for three to four days. After this time, cells were released from the flasks using trypsin and pipetting as described above. All other cells were sorted using

a FACSAria II cell sorter (BD Biosciences, San Jose, CA). Representative images were generated using FlowJo 8 (Tree Star, Inc, Ashland, OR).

Photomicrographs

Sorted cells were plated into 6-well tissue culture plates. When cells were at the desired level of confluency, photomicrographs were generated using a Nikon Eclipse TE2000E with 4x, 10x and 20x phase contrast objectives; Nikon DS-Qi1Mc CCD camera; and Nikon NIS Elements 3 software (Nikon Instruments Inc., Melville, NY).

Cell Size Analysis

Unsorted cells were trypsinized then stained with Aldefluor and propidium iodide as described above. Cells were analyzed on a FACSCalibur flow cytometer (BD Biosciences, San Jose, CA) and plots were generated using FlowJo 8.

Doubling Time

Sorted cells were plated into vented T25 tissue culture flasks with the medium they were cultured in prior to sorting. At 24-hour intervals ranging from 24 to 120 hours, cells were released from flasks with trypsin and pipetting as described above. FNAR-C1 cells grown in KnockOut medium and sorted for Aldefluor high tended to form aggregates, which were disrupted after trypsinization using Accumax and pipetting (EMD Millipore, Billerica, MA). Viable cells were counted by mixing cells

with an equal volume of trypan blue (Life Technologies, Grand Island, NY) and pipetting onto a hemacytometer (Hausser Scientific, Horsham, PA). Ten 1 mm² squares were counted and averaged to obtain the final cell count. Time points that appeared to be in lag phase or plateau phase were excluded from the doubling time calculations. Doubling times were calculated using an online doubling time calculator (Roth V. 2006 <http://www.doubling-time.com/compute.php>). Graphs were generated using Excel 2008 for Mac (Microsoft, Redmond, WA).

Cell Cycle Analysis

Sorted cells were allowed to recover overnight after sorting. No more than 5x10⁵ Aldefluor low FNAR-C1 or SKOV3 cells were plated into vented T75 tissue culture flasks with differentiation medium. 1.75x10⁵ Aldefluor high taxol-resistant SKOV3 cells were plated in a vented T25 tissue culture flask with KnockOut medium. Cells were released from flasks using trypsin and pipetting as described above. Aldefluor high FNAR-C1 cells were harvested from recovery flasks as described in Cell Sorting. No greater than 2.5x10⁵ cells were resuspended in 2 ml ice-cold PBS (Life Technologies, Grand Island, NY). Cells were fixed with the dropwise addition of 1 ml ice-cold methanol (Fisher, Waltham, MA) then incubated overnight at 4°C. Cells were rehydrated in PBS then stained with 50 µg/ml propidium iodide and 10 µg/ml RNase (Roche, Indianapolis, IN) in PBS for 30 minutes at room temperature. Data was collected on a FACSCalibur flow cytometer and analyzed using FlowJo 8.

Microarray and Pathway Analysis

Cells were sorted into RNeasy Protect Cell Reagent (Qiagen, Valencia, CA) to preserve RNA. Total RNA was isolated from sorted cells using the RNeasy Mini Kit with QIAshredder columns (Qiagen, Valencia, CA). Quality assessment and microarray analysis was performed at The Sidney Kimmel Cancer Center Microarray Core Facility at Johns Hopkins University, supported by NIH grant P30 CA006973 entitled Regional Oncology Research Center. RNA quality was determined with a NanoDrop ND-1000 spectrometer (Thermo Scientific, Waltham, MA) for OD_{260/280} and OD_{260/230} ratio and a 2100 Bioanalyzer (Agilent Technologies, Santa Clara, CA).

The following rat samples were analyzed: FNAR-C1 grown in differentiation medium and sorted for Aldefluor low, and FNAR-C1 grown in KnockOut medium and sorted for Aldefluor high. Rat samples were analyzed using the Rat Gene Expression Microarray 4x44K v3 (Agilent Technologies, Santa Clara, CA). Sample amplification and labeling procedures were carried out using the Low RNA Input Fluorescent Linear Amplification Kit (Agilent Technologies, Santa Clara, CA) with minor modifications. Briefly, 0.4 µg total RNA was reverse-transcribed into cDNA by MMLV-RT using an oligo(dT) primer that incorporates a T7 promoter sequence (System Biosciences, Mountain View, CA). The cDNA was then used as a template for *in vitro* transcription in the presence of T7 RNA polymerase and Cyanine-3 (Cy3) labeled CTP (Perkin Elmer, Waltham, MA). Labeled cRNA was purified using the

RNeasy Mini Kit. RNA spike-in controls (Agilent Technologies, Santa Clara, CA) were added to RNA samples before amplification and labeling according to manufacturer's protocol. 0.825 µg of each Cy3-labeled sample was used for hybridization at 65°C for 17 hours in a hybridization oven with rotation. After hybridization, microarrays were washed and dried according to the Agilent microarray processing protocol using Stabilization and Drying Solution (Agilent Technologies, Santa Clara, CA). Microarrays were scanned using an Agilent G2565AA Scanner controlled by Agilent Scan Control 7.0 software (Agilent Technologies, Santa Clara, CA). Data were extracted with Agilent Feature Extraction 9.5.3.1 software (Agilent Technologies, Santa Clara, CA).

The following human samples were analyzed: SKOV3 grown in differentiation medium and sorted for Aldefluor low, and taxol-resistant SKOV3 grown in KnockOut medium and sorted for Aldefluor high. Human samples were analyzed using the Human HT-12 v4 bead chip (Illumina, San Diego, CA). 500 ng of total RNA from each sample was amplified and labeled using the Illumina Total Prep RNA Amplification Kit (Ambion, Austin, TX) as described in the instruction manual. For array assay, 750 ng biotin-labeled cRNA was combined with hybridization buffer and hybridized to the array at 58°C for 16-20 hours. After hybridization, the hybridization cartridge was disassembled and the array was washed with buffer at 55°C and blocked at room temperature. Bound biotinylated cRNA was stained with streptavidin-Cy3 and then washed. Dried arrays were stored in a dark box until scanned with the iScan

System (Illumina, San Diego, CA). Data were extracted with the Gene Expression Module in GenomeStudio Software (Illumina, San Diego, CA).

Microarray data were further analyzed, especially for differentially regulated pathways, using iReport (Ingenuity® Systems, www.ingenuity.com, Redwood City, CA). Data from iReport only shows genes above the fold-change cutoff used for pathway analysis, which was 2.5 for FNAR-C1 cells and 1.5 for SKOV3 cells. For genes below the 1.5-fold SKOV3 cutoff and between 1.5- and 2.5-fold change in FNAR-C1 cells, data was analyzed using GeneSpring GX software version 11 (Agilent Technologies, Inc, Santa Clara, CA). Normalization was done with all intensities higher than 5, log2 transformation and cross-array quartile normalization. For FNAR-C1 genes below the 1.5-fold cutoff, fold-change was calculated manually from the Agilent Feature Extraction output.

PCR Validation of Microarray

PCR validation of microarray data used custom 96-well TaqMan array plates (Life Technologies, Grand Island, NY). For FNAR-C1 samples, RNA came from the same isolation as the microarray experiment. For SKOV3 samples, cells were sorted as described for the microarray. The rest of the procedure was performed at The Sidney Kimmel Cancer Center Microarray Core Facility at Johns Hopkins University, supported by NIH grant P30 CA006973 entitled Regional Oncology Research Center. RNA was isolated using TRIzol isolation followed by the RNeasy Mini Kit. cDNA synthesis was performed using the High Capacity RNA-to-cDNA Kit (Life

Technologies, Grand Island, NY). 20 ng of cDNA was added to each well of the custom TaqMan array plates along with TaqMan Universal PCR Master Mix (Life Technologies, Grand Island, NY) in a final volume of 20 μ l. Each sample was assayed in triplicate using three identical plates. Data was collected using the ABI 7500 Real-Time PCR System (Life Technologies, Grand Island, NY). Data was analyzed using 7500 Fast System SDS software version 1.4 (Life Technologies, Grand Island, NY). For FNAR-C1 samples, CXCL1 was used as the endogenous control. For SKOV3 samples, EEF1A1 was used as the endogenous control.

Regeneration of Phenotypic Diversity Assay

Sorted cells were plated into vented T25 tissue culture flasks with either KnockOut or differentiation medium. After four days of culture, cells were released from the plastic as described above and stained with Aldefluor and propidium iodide as described above. Cells were analyzed on a FACSCalibur flow cytometer. Plots were generated using FlowJo 8.

***In vivo* Tumorigenicity**

Cells were stained with Aldefluor and PI then sorted as described above. However, FNAR-C1 cells from KnockOut medium were sorted using a FACS Aria 1 or 2 and were not recovered in culture after sorting. Sorted cells were counted and resuspended in RPMI such that injection of 1 ml provided the desired cell dose. Female Lewis rats received intraperitoneal injections with graded numbers of cells.

Rats were monitored weekly and euthanized when becoming moribund or when tumors were detected by palpating the abdomen. Two years after the injection date, any remaining rats were euthanized and necropsy was performed to evaluate the presence of undetected cancer. All animals were handled in accordance with the Johns Hopkins University Animal Care and Use guidelines. All tumors underwent histological evaluation in a blinded manner to exclude any spontaneously occurring tumors. Statistical significance was calculated using the Fisher's Exact Test in EpiStat.

In Vitro Drug Resistance

Sorted cells were plated at a density of 100 cells per well into 24-well tissue culture plates with six wells per condition. FNAR-C1 cells were plated in differentiation medium with the following concentrations of paclitaxel (taxol): 10 nM, 20 nM, 40 nM, and 60 nM (ALDH^{high}: n=4; ALDH^{low}: n=5). Taxol-resistant SKOV3 cells were plated in differentiation medium with the following concentrations of taxol: 100 nM (n=6), 200 nM (n=7), 400 nM (n=8), 600 nM (n=7), and 800 nM (n=3); the following concentrations of carboplatin (Sigma-Aldrich, St. Louis, MO): 250 ng/ml (n=1), 500 ng/ml (n=5), 750 ng/ml (n=5), 1 µg/ml (n=5), and 1.25 µg/ml (n=4); and the following concentrations of gemcitabine (Gemzar; Eli Lilly and Company, Indianapolis, IN): 2 nM (n=3), 3 nM (n=3), 4 nM (n=5), 5 nM (n=5), 6 nM (n=2), and 7 nM (n=2). Cells were continuously exposed to taxol and gemcitabine. Cells were

incubated with carboplatin for 72 hours, which was then washed off and replaced with fresh medium. Cells were examined weekly with a Nikon Eclipse T1-S with 4x, 10x and 20x objectives (Nikon Instruments Inc., Melville, NY). Growth was defined as at least one colony of greater than ten cells in a well and data is presented as the percentage of wells that grew relative to no drug control. Data for FNAR-C1 cells is from two to four weeks of growth. Data for taxol-resistant SKOV3 cells is from two to three weeks of growth. Graphs were generated using Excel 2008 for Mac. Statistical significance was determined using Excel 2008 for Mac to calculate the unpaired, 2-tailed Student's t-test. For drug concentrations with only two data points per population, the unpaired, 2-tailed Student's t-test was calculated using GraphPad QuickCalcs (<http://www.graphpad.com/quickcalcs/ttest1/>).

Resistance to taxol was additionally evaluated by determining the percentage of ALDH^{high} cells remaining after treatment. Unsorted FNAR-C1 and SKOV3 cells were plated in differentiation medium with or without taxol. For FNAR-C1, n = 3 for no drug and n = 4 for taxol. Taxol doses ranged from 10 nM to 1 μ M for 72 hours. For SKOV3, five individual assays were performed comparing SKOV3 cells to taxol-resistant SKOV3 cells continuously cultured in the presence of 33.3 nM taxol. Cells were released from plastic then stained with Aldefluor and propidium iodide as described above. Data was collected on a FACSCalibur flow cytometer and analyzed using FlowJo 8. Plots were generated using Excel 2008 for Mac and p-values were calculated using the unpaired, 2-tailed Student's t-test.

4 Results

Aldefluor Defines Distinctive Populations

Initial observations of the FNAR-C1 rat model of ovarian cancer showed a small aldehyde dehydrogenase 1 high (ALDH^{high}) population, as measured with the Aldefluor reagent. However, continued culture in standard medium containing serum resulted in the loss of ALDH^{high} cells. Serum has been reported to promote the differentiation of stem cell populations; and for this reason, standard medium with serum will be referred to as differentiation medium¹²³⁻¹²⁶. Despite numerous attempts, it was not possible to identify a culture condition that maintained both ALDH^{high} and ALDH^{low} populations. However, culturing FNAR-C1 cells in Knockout medium,

which is a proprietary, serum-free medium designed for the maintenance of embryonic stem cells in an undifferentiated state, maintained a large ALDH^{high} population.

Figure 4.1: Aldefluor Sorting

Representative samples of sorting gates are shown. All gating used DEAB as a negative control. (A) FNAR-C1 cells grown in differentiation medium were sorted for the Aldefluor low population. (B) FNAR-C1 cells grown in KnockOut medium were sorted for the Aldefluor high population. (C) SKOV3 cells grown in differentiation medium were sorted for the Aldefluor low population. (D) Taxol-resistant SKOV3 cells grown in differentiation medium were sorted for the Aldefluor low population. (E) Taxol-resistant SKOV3 cells grown in KnockOut medium were sorted for the Aldefluor high population.

Therefore, in order to study the biology of both ALDH^{high} and ALDH^{low} populations, two different culture conditions were used. When stained with Aldefluor, FNAR-C1 cells cultured in differentiation medium were predominantly ALDH^{low} (Figure 4.1A). Occasional ALDH^{high} cells were seen, but they were scattered and diffuse and did not appear to represent a distinct population (mean = 2.05%, range = 0.23 – 9.3%). When FNAR-C1 cells were grown in KnockOut medium, two clearly defined populations were seen, with ALDH^{high} cells representing approximately half of the cells (Figure 4.1B; mean = 56.88%, range = 15.7 – 86.5%). It was hypothesized that ALDH^{high} cells from KnockOut medium would represent a primitive stem-like population and ALDH^{low} cells from differentiation medium would represent a differentiated cell population. Therefore, these were the two populations analyzed.

Like FNAR-C1 cells, SKOV3 cells cultured in differentiation medium showed few ALDH^{high} cells (Figure 4.1C; mean = 2.12%, range = 0.18 – 6.28%). In contrast to the FNAR-C1 cells, culture of SKOV3 cells in KnockOut medium did not substantially change the percentage of ALDH^{high} cells (data not shown). However, when SKOV3 cells obtained taxol-resistance, a distinct ALDH^{high} population emerged in differentiation medium (Figure 4.1D; mean = 3.25%, range = 1.18 – 12.1%). Furthermore, culturing taxol-resistant SKOV3 cells in KnockOut medium resulted in a predominantly ALDH^{high} population (Figure 4.1E; mean = 20.22, range = 10.0% to 42.2%). The cancer stem cell model proposes that cancer stem cells are relatively drug-resistant. Therefore, it was hypothesized that ALDH^{high} taxol-resistant SKOV3

cells from KnockOut medium might represent a stem cell-like population and ALDH^{low} SKOV3 cells from differentiation medium could represent a differentiated population, and so these were the principal populations studied.

In order to test these hypotheses, each distinct ALDH population was examined for commonly accepted stem cell properties. These properties included nonadherent growth, quiescence, a lack of contact inhibition, size, the ability to regenerate the phenotypic diversity of the cell line, tumorigenicity and drug resistance¹²⁷⁻¹³³. Finally, expression patterns consistent with a stem cell phenotype were analyzed.

ALDH^{high} Cells Share Morphological and Growth Characteristics With Cancer Stem Cells

Commonly accepted properties of stem cells include non-adherent growth and the absence of contact inhibition¹²⁸. FNAR-C1 cells grow adherently on plastic. Upon reaching confluency, ALDH^{low} cells showed substantial death, which resulted in large areas devoid of cells (data not shown). ALDH^{high} FNAR-C1 cells failed to undergo growth arrest upon achieving confluency and instead formed large three-dimensional clusters of cells, termed nodules (Figure 4.2A). These data suggest that ALDH^{low} cells retained contact inhibition, but ALDH^{high} cells lacked contact inhibition. In addition to forming nodules, a portion of ALDH^{high} FNAR-C1 cells grew as nonadherent clusters, termed spheroids (Figure 4.2B). Supernatant from ALDH^{low} FNAR-C1 cell cultures only showed apoptotic cells and cellular debris,

without any viable cell aggregates (data not shown). ALDH^{high} taxol-resistant SKOV3 cells also displayed nonadherent growth through the formation of spheroids (Figure 4.2C), which was not observed in ALDH^{low} SKOV3 cells (data not shown). Consistent with a stem cell phenotype, ALDH^{high} cells lack contact inhibition and possess the capacity for nonadherent growth, which are features not observed in ALDH^{low} cells.

Figure 4.2: Nodules and Spheroids

Pictomicrographs showing nodules (A) and spheroid (B) in ALDH^{high} FNAR-C1 cells and spheroid in ALDH^{high} taxol-resistant SKOV3 cells (C). For photography of ALDH^{high} FNAR-C1 spheroids, the supernatant was moved to an empty well. All images used a 20x phase contrast objective.

Figure 4.3: Cell Size

Unsorted cells were stained for Aldefluor and gated on the population of interest using DEAB as a negative control. The forward scatter, or size, of these cells was then displayed. (A) FNAR-C1 cells are shown with ALDH^{high} in red and ALDH^{low} in blue. (B) SKOV3 cells are shown. ALDH^{high} taxol-resistant SKOV3 cells are in red and ALDH^{low} SKOV3 cells are in blue.

Stem cells are typically smaller in size than their differentiated counterparts¹²⁷.
¹²⁹. Consistent with this, ALDH^{high} cells from both FNAR-C1 and taxol-resistant SKOV3 cells were smaller than ALDH^{low} cells from FNAR-C1 and SKOV3 cells, respectively (Figure 4.3). This smaller size is often attributed to the relative

quiescence of stem cells^{132, 133}. ALDH^{high} FNAR-C1 cells had a doubling time of 32.2 hours compared to a doubling time of 15.6 hours for ALDH^{low} cells (Figure 4.4A).

Figure 4.4: Growth Curves

Sorted cells were counted at 24-hour intervals. (A) FNAR-C1 cells are shown with ALDH^{high} in red and ALDH^{low} in blue. (B) SKOV3 cells are shown. ALDH^{high} taxol-resistant SKOV3 cells are in red and ALDH^{low} SKOV3 cells are in blue.

ALDH^{high} taxol-resistant SKOV3 cells showed a similarly increased doubling time of 39.6 hours relative to 27.0 hours in ALDH^{low} SKOV3 cells (Figure 4.4B). These data reveal a slower growth rate in the ALDH^{high} cells of both models. This difference could be attributed to decreased proliferation or increased apoptosis. Cell cycle analysis distinguished between these two possibilities. ALDH^{high} FNAR-C1 cells had fewer dividing cells than ALDH^{low} FNAR-C1 cells with 52.8% of ALDH^{high} cells in the G1/G0 phase of the cell cycle versus 30.5% of ALDH^{low} cells (Figure 4.5A, B). This observation was confirmed in the SKOV3 model with 53.4% of ALDH^{high} taxol-resistant SKOV3 cells in the G1/G0 phase but only 42.2% of ALDH^{low} SKOV3

(Figure 4.5C, D). None of the populations showed a substantial sub-G1 cell population that would indicate apoptosis. Therefore, the increased doubling times of ALDH^{high} cells are the result of decreased proliferation.

Figure 4.5: Cell Cycle Analysis

Representative cell cycle analyses using propidium iodide are shown: (A) ALDH^{low} FNAR-C1 cells, (B) ALDH^{high} FNAR-C1 cells, (C) ALDH^{low} SKOV3 cells, (D) ALDH^{high} taxol-resistant SKOV3 cells.

Microarray data showed that the decreased proliferation of ALDH^{high} cells is due to a block at the G1/S checkpoint. ALDH^{high} FNAR-C1 cells had downregulation of genes important for progression from G1 to S phase relative to ALDH^{low} FNAR-C1 cells (Figure 4.6). ALDH^{high} FNAR-C1 cells showed 3.512-fold (3.922-fold by PCR)

downregulation of c-myc and 5.704-fold downregulation of neuregulin 1, both of which promote cell cycle progression^{134, 135}. Cyclin D1 stimulates the G1/S transition by complexing with cyclin dependent kinases 4 or 6 and was downregulated 2.503-fold (2.227-fold by PCR) in ALDH^{high} FNAR-C1 cells¹³⁶. Additionally, cyclin D1 may play a role in exiting quiescence¹³⁷. Downregulation of these crucial components of the G1/S checkpoint in ALDH^{high} FNAR-C1 cells suggests a block in cell cycle progression.

Differential regulation of genes in ALDH^{high} taxol-resistant SKOV3 cells compared to ALDH^{low} SKOV3 cells supports the same conclusion (Figure 4.7). ALDH^{high} taxol-resistant SKOV3 cells showed 2.22-fold downregulation (2.532-fold by PCR) of cyclin dependent kinase 6, which complexes with cyclin D1 to trigger the G1/S transition¹³⁸. Transcription factor DP-1 (TFDP1) and ABL1 are components of the Rb/E2F pathway that is required for progression from G1 to S phase¹³⁹⁻¹⁴². TFDP1 was downregulated 1.58-fold (1.526-fold by PCR) and ABL1 was 2.10-fold downregulated (3.086-fold by PCR) in ALDH^{high} taxol-resistant SKOV3 cells. In addition to downregulation of components of the G1/S checkpoint, ALDH^{high} taxol-resistant SKOV3 cells showed 2.28-fold overexpression (2.741-fold by PCR) of cyclin-dependent kinase inhibitor 1A (CDKN1A). CDKN1A inhibits cyclin dependent kinases 2 and 4, which are important components of the G1/S transition¹⁴³. Overall, ALDH^{high} cells show a block at the G1/S checkpoint that results in fewer cycling cells and a decreased growth rate.

Figure 4.6: G1/S Arrest of ALDH^{high} FNAR-C1 Cells

Pathway analysis of microarray data. Data is presented as ALDH^{high} FNAR-C1 cells relative to ALDH^{low} FNAR-C1 cells. Genes shaded in yellow were upregulated and genes shaded in blue were downregulated.

Figure 4.7: G1/S Arrest of ALDH^{high} Taxol-Resistant SKOV3 Cells

Pathway analysis of microarray data. Data is presented as ALDH^{high} taxol-resistant SKOV3 cells relative to ALDH^{low} SKOV3 cells. Genes shaded in yellow were upregulated and genes shaded in blue were downregulated.

ALDH^{high} Cells Are Capable of Regenerating the Phenotypic Diversity of the Cell Line and Are Tumorigenic *In Vivo*

Cancer stem cells should reconstitute the phenotypic heterogeneity of the tumor, while differentiated cells would not be expected to do so^{128, 130-133}. ALDH^{low} FNAR-C1 (Figure 4.8C, D) and SKOV3 (Figure 4.9C, D) cells only produced ALDH^{low} cells *in vitro*, even when cultured in KnockOut medium that supports the growth of ALDH^{high} cells. Conversely, ALDH^{high} FNAR-C1 (Figure 4.8A, B) and taxol-resistant SKOV3 (Figure 4.9A, B) cells remained ALDH^{high} when cultured in KnockOut medium but rapidly generated ALDH^{low} cells in differentiation medium.

Figure 4.8: Regeneration of Phenotypic Diversity in FNAR-C1 Cells

Accordingly, ALDH^{high}, but not ALDH^{low}, cells regenerate the phenotypic diversity of the cell lines, suggesting that ALDH^{high} cells represent a less differentiated phenotype than ALDH^{low} cells.

Figure 4.9: Regeneration of Phenotypic Diversity in SKOV3 Cells

The gold standard assay for cancer stem cells is increased *in vivo* tumorigenicity^{128, 131-133}. In order to test the tumorigenicity of ALDH^{high} and ALDH^{low} cells, graded numbers of sorted FNAR-C1 cells were injected intraperitoneally into immunocompetent Lewis rats (Table 4.1). The only rats to develop tumors were those receiving ALDH^{high} cells. None of the rats injected with ALDH^{low} cells developed tumors. This provides *in vivo* support for the conclusion that ALDH^{high} cells represent the tumorigenic population within FNAR-C1 cells.

Table 4.1: *In Vivo* Tumorigenicity of FNAR-C1 Cells

	100,000 cells	1,000 cells
ALDH ^{high}	3/16 (148, 177, 222)	1/12 (222)
ALDH ^{low}	0/8	0/9

This table shows the number of rats that formed abdominal tumors out of the total number injected with sorted FNAR-C1 cells. In parenthesis are days post-injection until tumors were detected.

Figure 4.10: Drug Sensitivity

Sorted cells were assayed for their ability to grow in increasing concentrations of drugs. ALDH^{high} cells grown are shown in red, and ALDH^{low} cells are shown in blue. Error bars show the standard error. (A) FNAR-C1 cells cultured with taxol. (B-D) Taxol-resistant SKOV3 cells cultured in: (B) taxol, (C) carboplatin and (D) gemcitabine.

ALDH^{high} Cells Display Multi-Drug Resistance

The cancer stem cell hypothesis proposes that cancer stem cells are more resistant to chemotherapy and are therefore responsible for relapse¹³¹⁻¹³³. To test the relative drug sensitivities of ALDH^{high} and ALDH^{low} populations, cells were incubated with increasing doses of drugs and examined for growth. ALDH^{high} FNAR-C1 cells showed increased resistance to taxol with an IC50 of 37.4 nM versus an IC50 of 13.6 nM for ALDH^{low} FNAR-C1 cells (Figure 4.10A). The differences in drug sensitivity were statistically significant at the 20 nM ($p = 0.015$) and 40 nM ($p = 0.023$) doses. When examining the sensitivities of SKOV3 cells, it was inappropriate to compare taxol-resistant cells to taxol-sensitive cells. Not only would this comparison produce invalid results for taxol, but also taxol-resistant cells were continuously cultured in the presence of taxol and would therefore be exposed to combination drug treatment when examining carboplatin and gemcitabine sensitivities. For these reasons, ALDH^{high} taxol-resistant SKOV3 cells grown in KnockOut medium were compared to ALDH^{low} taxol-resistant SKOV3 cells grown in differentiation medium. Taxol, carboplatin and gemcitabine were chosen because they each have different mechanisms of action and resistance. ALDH^{high} taxol-resistant SKOV3 cells showed increased resistance to taxol with an IC50 of 427 nM compared to an IC50 of 224 nM for ALDH^{low} taxol-resistant cells (Figure 4.10B). The observed differences in sensitivity were statistically significant at two doses (400 nM, $p=0.008$; 600 nM, $p=0.035$). These results were unexpected since both populations are grown in taxol. ALDH^{high} taxol-

resistant SKOV3 cells also showed a trend towards increased carboplatin resistance. The IC₅₀ of ALDH^{high} taxol-resistant SKOV3 cells was 903 ng/ml and the IC₅₀ of ALDH^{low} taxol-resistant SKOV3 cells was 700 ng/ml (Figure 4.10C). These results approached statistical significance with a p-value of 0.08 at the 1 µg/ml carboplatin dose. Finally, gemcitabine resistance was also demonstrated in ALDH^{high} taxol-resistant SKOV3 cells. ALDH^{low} taxol-resistant SKOV3 cells had an IC₅₀ of 4.3 nM, but ALDH^{high} taxol-resistant SKOV3 cells had more than 50% growth at all doses tested and so the IC₅₀ was predicted to be 7.5 nM (Figure 4.10D). The differential sensitivities were statistically significant at two doses (5 nM, p = 0.0006; 6 nM, p = 0.0128). Therefore, ALDH^{high} cells displayed resistance to chemotherapy drugs with different mechanisms of resistance, consistent with the multi-drug resistance of stem cells.

As an additional measure of drug resistance, the change in percentage of ALDH^{high} cells after exposure to taxol was determined. When unsorted FNAR-C1 cells in differentiation medium were exposed to taxol, the percentage of ALDH^{high} cells increased from a mean of 1.1% to 4.1% (p = 0.04; Figure 4.11A). Similarly, taxol-resistant SKOV3 cells in differentiation medium had an increased ALDH^{high} population (mean = 4.1%) compared to taxol-sensitive SKOV3 cells cultured in differentiation medium (mean = 0.4%, p = 0.024; Figure 4.11B). This suggests that drug treatment enriches for ALDH^{high} cells, likely due to selective elimination of ALDH^{low} cells, and that this occurs even under conditions that do not support the

growth of stem cells. The increased resistance of ALDH^{high} cells was associated with upregulation of the multi-drug resistance 1 (MDR1) gene (ABCB1 in humans and ABCB1B in rats), which is an ATP-binding cassette transporter that functions in drug efflux and is a primary mechanism of taxol resistance¹⁴⁴. ALDH^{high} FNAR-C1 cells displayed 16.797-fold upregulation (24.603-fold by PCR) of ABCB1B compared to ALDH^{low} FNAR-C1 cells (Table 4.2, pg. 98). ABCB1 was 3.743-fold upregulated (374.276-fold by PCR) in ALDH^{high} taxol-resistant SKOV3 cells compared to ALDH^{low} SKOV3 cells (Table 4.2, pg. 98). Therefore, increased expression of the MDR1 gene may contribute to taxol resistance in ALDH^{high} cells and their enrichment after taxol treatment. However, MDR1 plays no role in gemcitabine or carboplatin resistance.

Figure 4.11: Percentage of ALDH^{high} Cells After Taxol Treatment

Unsorted FNAR-C1 (A) and SKOV3 (B) cells were cultured in differentiation medium with or without taxol. The percentage of ALDH^{high} cells was then measured.

ALDH^{high} Cells' Gene Expression Is Consistent With a Stem Cell Phenotype

Microarray analysis examined gene expression patterns consistent with a stem cell phenotype. The embryonic stem cell pluripotency pathway in FNAR-C1 cells is shown in Figure 4.12 (pg. 62). Data are presented as ALDH^{high} FNAR-C1 cells versus ALDH^{low} FNAR-C1 cells. ALDH^{high} FNAR-C1 cells showed upregulation of WNT2B (92.03-fold by microarray, 581.598-fold by PCR), WNT4 (10.745-fold by microarray, 18.296-fold by PCR) and WNT11 (8.719-fold by microarray, 15.722-fold by PCR)¹⁴⁵. Each of these WNT genes has been shown to play important roles in stem cells. Embryonic stem cells express WNT2B¹⁴⁶. Additionally, WNT2B is associated with metastasis and chemoresistance in ovarian cancer¹⁴⁷. WNT4 is important in progenitor cell expansion^{148, 149}. Finally, WNT11 has been shown to maintain proliferating stem cells in the presence of retinoic acid¹⁵⁰. Also in the Wnt/ β -catenin pathway is the TCF/LEF complex that is important for stem cell self-renewal^{151, 152}. ALDH^{high} FNAR-C1 cells exhibited 3.225-fold upregulation (88.626-fold by PCR) of LEF1 and 4.192-fold upregulation (6.754-fold by PCR) of TCF7L1.

In addition to WNT family members, other stem cell associated genes were upregulated in ALDH^{high} FNAR-C1 cells. Platelet-derived growth factor β , which is involved in stem cell maintenance, was upregulated 3.192-fold (12.254-fold by PCR) in ALDH^{high} FNAR-C1 cells^{153, 154}. Brain-derived neurotrophic factor was 5.886-fold (6.567-fold by PCR) upregulated in ALDH^{high} FNAR-C1 cells and can induce stem cell proliferation¹⁵⁵. Stem cells express high levels of neurotrophin 3, and ALDH^{high}

FNAR-C1 cells demonstrated 3.18-fold upregulation¹⁵⁶. Fibroblast growth factor receptors (FGFR) 1 and 2 are required for the maintenance of a diverse array of stem cells^{157, 158}. FGFR1 was 3.736-fold upregulated (24.101-fold by PCR) and FGFR2 was 22.621-fold upregulated (33.065-fold by PCR) in ALDH^{high} FNAR-C1 cells. Bone morphogenetic protein 7, which was 4.44-fold upregulated (3.329-fold by PCR) in ALDH^{high} FNAR-C1 cells, is important for the survival and proliferation of progenitor cells¹⁵⁹. Accordingly, ALDH^{high} FNAR-C1 cells showed upregulation of numerous genes that serve crucial functions in the maintenance, self-renewal and proliferation of stem cells.

The embryonic stem cell pluripotency pathway in Figure 4.13 (pg. 63) displays genes differentially regulated in ALDH^{high} taxol-resistant SKOV3 cells relative to ALDH^{low} SKOV3 cells. Despite some dissimilarity with ALDH^{high} FNAR-C1 cells, ALDH^{high} taxol-resistant SKOV3 cells also demonstrated an expression pattern consistent with a stem cell phenotype. ALDH^{high} taxol-resistant SKOV3 cells showed 1.58-fold upregulation of the regulatory subunit of phosphoinositide-3-kinase, which is important in breast cancer stem cells¹⁶⁰. SMAD3 signaling maintains stem cell pluripotency and was upregulated 1.66-fold in ALDH^{high} taxol-resistant SKOV3 cells¹⁶¹. Self-renewal of stem cells is strongly influenced by bone morphogenetic protein 4 (BMP4)¹⁶². Accordingly, ALDH^{high} taxol-resistant SKOV3 cells demonstrated 5.67-fold upregulation of BMP4. Bone morphogenetic protein 5 has the capacity to increase the number of stem cells and ALDH^{high} taxol-resistant SKOV3

cells displayed 3.01-fold (117.407-fold by PCR) upregulation versus ALDH^{low} SKOV3 cells¹⁶³. In addition to upregulation of stem cell associated genes, ALDH^{high} taxol-resistant SKOV3 cells showed downregulation of a gene associated with differentiation: bone morphogenetic protein 1 (1.55-fold downregulation)¹⁶⁴. Similar to ALDH^{high} FNAR-C1 cells, ALDH^{high} taxol-resistant SKOV3 cells exhibited upregulation of genes that control vital properties of stem cells and downregulation of a gene involved in differentiation.

ALDH^{high} cells additionally showed differential regulation of genes in the OCT4 pathway consistent with a stem cell phenotype. Figure 4.14 (pg. 64) shows ALDH^{high} FNAR-C1 cells compared to ALDH^{low} FNAR-C1 cells. NR2F1 was 2.625-fold upregulated in ALDH^{high} FNAR-C1 cells and has been reported to induce quiescence¹⁶⁵. CDX2 induces differentiation and was downregulated 12.968-fold in ALDH^{high} FNAR-C1 cells¹⁶⁶. Therefore, differential expression of genes in the OCT4 pathway suggests that ALDH^{high} FNAR-C1 cells exhibit a more primitive phenotype than their ALDH^{low} counterparts. Figure 4.15 (pg. 65) presents the OCT4 pathway in ALDH^{high} taxol-resistant SKOV3 cells relative to ALDH^{low} SKOV3 cells. ALDH^{high} taxol-resistant SKOV3 cells displayed 3.74-fold upregulation (3.298-fold by PCR) of the downstream effector secreted phosphoprotein 1, which is highly expressed in stem and progenitor cells¹⁶⁷. Observations in both models suggest the OCT4 pathway plays a role in the maintenance of a stem cell phenotype in ALDH^{high} cells.

Figure 4.12: FNAR-C1 Embryonic Stem Cell Pluripotency

ALDH^{high} Cells Represent a Biologically Distinct Population

Data presented thus far show that ALDH^{high} cells represent a stem cell-like population within ovarian cancer. Therefore, studying gene expression differences in these cells should reveal biological properties of ovarian cancer stem cells. The FNAR-C1 and SKOV3 models represent different ovarian cancer subtypes. By examining microarray data for those features that are consistently differentially regulated in the ALDH^{high} cells of both models, it may be possible to identify properties of ovarian cancer stem cells that would be representative of all patients, rather than those with a specific subtype.

For microarray analysis, cells were isolated based on different levels of Aldefluor staining. In order to validate the Aldefluor staining patterns in isolated cells with aldehyde dehydrogenase 1 (ALDH1) expression, the expression levels of ALDH1 family members were examined. The enzymes of the ALDH1 family are also known as retinaldehyde dehydrogenases. Although the precise function of ALDH1 enzymes in stem-cell biology is unclear, the major biological function of the ALDH1 family appears to be the biosynthesis of retinoic acid, the active metabolite of vitamin A (retinol). ALDH1 catalyzes the final step of this process, the oxidation of retinaldehyde to retinoic acid¹⁶⁸. There are three known members of the family, ALDH1A1, A2, and A3, with somewhat redundant expression and function. In ALDH^{high} FNAR-C1 cells, there was 86.522-fold upregulation (325.761-fold by PCR) of ALDH1A2 relative to ALDH^{low} FNAR-C1 cells (Table 4.2, pg. 98). ALDH^{high}

taxol-resistant SKOV3 cells expressed ALDH1A1 at a 23.699-fold greater level (44.494-fold by PCR) than ALDH^{low} SKOV3 cells (Table 4.2, pg. 98). Not only does this confirm that Aldefluor high cells have the expected increased expression of ALDH1, it suggests that there may be species differences with regard to specific isoenzyme expression.

Tight junctions form barriers that prevent diffusion of molecules between epithelial cells. Additionally, signaling through tight junction proteins regulates cellular behavior. Both models exhibited upregulation of tight junction genes in ALDH^{high} cells suggesting a role for this pathway in ovarian cancer stem cells. Figure 4.16 presents the expression of tight junction genes in ALDH^{high} FNAR-C1 cells relative to ALDH^{low} FNAR-C1 cells, and Figure 4.17 represents ALDH^{high} taxol-resistant SKOV3 cells compared to ALDH^{low} SKOV3 cells. Claudin genes, the primary proteins that form tight junctions and regulate their permeability, were upregulated in ALDH^{high} cells (FNAR-C1: claudin 23; SKOV3: claudins 1 and 3, confirmed by PCR). A second class of tight junction genes, junctional adhesion molecules (JAM), exhibited differential regulation in ALDH^{high} FNAR-C1 cells with 2.96-fold upregulation of JAM3 (4.882-fold by PCR). Both models also showed upregulation of multiple intracellular signaling components. Although it is clear that ALDH^{high} cells have the capacity for increased tight junction formation and intracellular signaling, the strength of the barriers formed is less certain.

Figure 4.16: FNAR-C1 Tight Junction Signaling

Pathway analysis of microarray data. Data is presented as ALDH^{high} FNAR-C1 cells relative to ALDH^{low} FNAR-C1 cells. Genes shaded in yellow were upregulated and genes shaded in blue were downregulated.

The diagram illustrates the signaling pathways and protein interactions between a Ciliated epithelial cell (left) and a Non-ciliated epithelial cell (right). Key components and interactions include:

- Ciliated Epithelial Cell (Left):**
 - Receptors and Ligands:** TGF- β (ligand), TGF- β R (receptor), TNF- α (ligand), TNF- α R (receptor).
 - Integrins and Cytoskeleton:** Fodrin, 4.1R, Nectin, Afadin, MUPP1, ZO1, ZO2, ZO3, ZO4, ZO5, ZO6, ZO7, ZO8, ZO9, ZO10, ZO11, ZO12, ZO13, ZO14, ZO15, ZO16, ZO17, ZO18, ZO19, ZO20, ZO21, ZO22, ZO23, ZO24, ZO25, ZO26, ZO27, ZO28, ZO29, ZO30, ZO31, ZO32, ZO33, ZO34, ZO35, ZO36, ZO37, ZO38, ZO39, ZO40, ZO41, ZO42, ZO43, ZO44, ZO45, ZO46, ZO47, ZO48, ZO49, ZO50, ZO51, ZO52, ZO53, ZO54, ZO55, ZO56, ZO57, ZO58, ZO59, ZO60, ZO61, ZO62, ZO63, ZO64, ZO65, ZO66, ZO67, ZO68, ZO69, ZO70, ZO71, ZO72, ZO73, ZO74, ZO75, ZO76, ZO77, ZO78, ZO79, ZO80, ZO81, ZO82, ZO83, ZO84, ZO85, ZO86, ZO87, ZO88, ZO89, ZO90, ZO91, ZO92, ZO93, ZO94, ZO95, ZO96, ZO97, ZO98, ZO99, ZO100.
 - Signaling Molecules:** RhoA, Rac1, Cdc42, PI3K, Akt, PTEN, VASP, Myosin, PRKAG2, PKA, PKC, MARK2, Rac1, Cdc42, PI3K, Akt, PTEN, VASP, Myosin, PRKAG2, PKA, PKC, MARK2.
 - Protein Interactions:** ZO1, ZO2, ZO3, ZO4, ZO5, ZO6, ZO7, ZO8, ZO9, ZO10, ZO11, ZO12, ZO13, ZO14, ZO15, ZO16, ZO17, ZO18, ZO19, ZO20, ZO21, ZO22, ZO23, ZO24, ZO25, ZO26, ZO27, ZO28, ZO29, ZO30, ZO31, ZO32, ZO33, ZO34, ZO35, ZO36, ZO37, ZO38, ZO39, ZO40, ZO41, ZO42, ZO43, ZO44, ZO45, ZO46, ZO47, ZO48, ZO49, ZO50, ZO51, ZO52, ZO53, ZO54, ZO55, ZO56, ZO57, ZO58, ZO59, ZO60, ZO61, ZO62, ZO63, ZO64, ZO65, ZO66, ZO67, ZO68, ZO69, ZO70, ZO71, ZO72, ZO73, ZO74, ZO75, ZO76, ZO77, ZO78, ZO79, ZO80, ZO81, ZO82, ZO83, ZO84, ZO85, ZO86, ZO87, ZO88, ZO89, ZO90, ZO91, ZO92, ZO93, ZO94, ZO95, ZO96, ZO97, ZO98, ZO99, ZO100.
- Non-ciliated Epithelial Cell (Right):**
 - Receptors and Ligands:** ZO1, ZO2, ZO3, ZO4, ZO5, ZO6, ZO7, ZO8, ZO9, ZO10, ZO11, ZO12, ZO13, ZO14, ZO15, ZO16, ZO17, ZO18, ZO19, ZO20, ZO21, ZO22, ZO23, ZO24, ZO25, ZO26, ZO27, ZO28, ZO29, ZO30, ZO31, ZO32, ZO33, ZO34, ZO35, ZO36, ZO37, ZO38, ZO39, ZO40, ZO41, ZO42, ZO43, ZO44, ZO45, ZO46, ZO47, ZO48, ZO49, ZO50, ZO51, ZO52, ZO53, ZO54, ZO55, ZO56, ZO57, ZO58, ZO59, ZO60, ZO61, ZO62, ZO63, ZO64, ZO65, ZO66, ZO67, ZO68, ZO69, ZO70, ZO71, ZO72, ZO73, ZO74, ZO75, ZO76, ZO77, ZO78, ZO79, ZO80, ZO81, ZO82, ZO83, ZO84, ZO85, ZO86, ZO87, ZO88, ZO89, ZO90, ZO91, ZO92, ZO93, ZO94, ZO95, ZO96, ZO97, ZO98, ZO99, ZO100.
 - Signaling Molecules:** RhoA, Rac1, Cdc42, PI3K, Akt, PTEN, VASP, Myosin, PRKAG2, PKA, PKC, MARK2.
 - Protein Interactions:** ZO1, ZO2, ZO3, ZO4, ZO5, ZO6, ZO7, ZO8, ZO9, ZO10, ZO11, ZO12, ZO13, ZO14, ZO15, ZO16, ZO17, ZO18, ZO19, ZO20, ZO21, ZO22, ZO23, ZO24, ZO25, ZO26, ZO27, ZO28, ZO29, ZO30, ZO31, ZO32, ZO33, ZO34, ZO35, ZO36, ZO37, ZO38, ZO39, ZO40, ZO41, ZO42, ZO43, ZO44, ZO45, ZO46, ZO47, ZO48, ZO49, ZO50, ZO51, ZO52, ZO53, ZO54, ZO55, ZO56, ZO57, ZO58, ZO59, ZO60, ZO61, ZO62, ZO63, ZO64, ZO65, ZO66, ZO67, ZO68, ZO69, ZO70, ZO71, ZO72, ZO73, ZO74, ZO75, ZO76, ZO77, ZO78, ZO79, ZO80, ZO81, ZO82, ZO83, ZO84, ZO85, ZO86, ZO87, ZO88, ZO89, ZO90, ZO91, ZO92, ZO93, ZO94, ZO95, ZO96, ZO97, ZO98, ZO99, ZO100.

69

Not present in the pathway analysis is CXADR, which is important for tight junction integrity and was upregulated in ALDH^{high} cells of both models (Table 4.2, pg. 98)^{169, 170}. This would suggest that ALDH^{high} cells form robust barriers. However, ALDH^{high} cells also displayed upregulation of several genes that increase tight junction permeability, including protein phosphatase 2A (PP2A) family members in both models and myosin light chain kinase in FNAR-C1 cells (MYLK: 89.956-fold by PCR)^{171, 172}. While the integrity of tight junctions formed by ALDH^{high} cells is uncertain, it is apparent that tight junction signaling may play an important role in ALDH^{high} cells. Additionally, the tendency of ALDH^{high} cells to grow as clusters and form spheroids may be due to increased formation of tight junctions.

Differential gene expression suggests that ALDH^{high} cells may represent tumor initiating cells. Tumor suppressors in the kruppel-like factor, S100 calcium binding protein and epithelial membrane protein families were downregulated in ALDH^{high} cells (Table 4.4, pg. 102)¹⁷³⁻¹⁷⁸. ALDH^{high} cells also appear to have an increased capacity for invasion. ALDH^{high} FNAR-C1 cells displayed upregulation of bone morphogenetic protein 7, cadherin 11, protein tyrosine kinase 7, matrix metalloproteinase 2 and matrix metalloproteinase 14 (Table 4.4, pg. 102)¹⁷⁹⁻¹⁸². Different members of the same gene families were upregulated in ALDH^{high} taxol-resistant SKOV3 cells, comprising bone morphogenetic protein 4, protein tyrosine kinase 2 and matrix metalloproteinase 7 (Table 4.4, pg. 102)¹⁸³⁻¹⁸⁵. These genes have been shown to induce migration and invasion, so upregulation implies that ALDH^{high}

cells represent the invasive population of tumor cells. Further supporting this conclusion is downregulation of inhibitors of extracellular matrix degradation. SERPINB2 was downregulated in ALDH^{high} FNAR-C1 cells, as was SERPINE1 in ALDH^{high} taxol-resistant SKOV3 cells (Table 4.4, pg. 103)^{186, 187}. Not only do ALDH^{high} cells have an increased capacity for invasion, but this process is aided by reduced deposition of the extracellular matrix. Collagen components of the basement membrane exhibited reduced expression in ALDH^{high} cells (Table 4.4, pg. 103)¹⁸⁸⁻¹⁹¹. Additionally, the transmembrane collagen COL17A1 was downregulated in ALDH^{high} cells of both models (Table 4.3, pg. 100)¹⁹². The formation of mature collagen fibers requires processing of procollagen molecules. ALDH^{high} cells showed downregulation of PCOLCE2, which binds to procollagen to enhance its cleavage, and downregulation of P4HA2, which is a component of the key collagen synthesis enzyme prolyl 4-hydroxylase (Table 4.3, pg. 100)^{193, 194}. In addition to reduced collagen expression and processing, laminin components of the basement membrane were also downregulated in ALDH^{high} cells, including LAMB3 and LAMC2 (Table 4.3, pg. 100)¹⁹⁵. The apparent reduced extracellular matrix deposition seen in ALDH^{high} cells would facilitate invasion by diminishing the amount of extracellular matrix degradation required. These observations suggest that ALDH^{high} cells display an increased capacity for migration and invasion, potentially indicating a role in metastasis.

Expression patterns in both models suggest decreased coagulation in ALDH^{high} cells. Figure 4.18 displays the expression of coagulation genes in ALDH^{high} FNAR-C1 cells compared to ALDH^{low} FNAR-C1 cells, and Figure 4.19 shows ALDH^{high} taxol-resistant SKOV3 cells relative to ALDH^{low} SKOV3 cells. In ALDH^{high} cells, coagulation was primarily inhibited via upregulation of tissue factor pathway inhibitor (TFPI), which blocks the extrinsic pathway of the coagulation cascade (Table 4.2, pg. 98)¹⁹⁶. Additionally, ALDH^{high} taxol-resistant SKOV3 cells exhibited 1.87-fold downregulation of fibrin, further reducing clot formation¹⁹⁷. Inhibition of the extrinsic coagulation pathway has intriguing implications in ovarian cancer. The extrinsic pathway is activated by tissue damage, which is likely to result if cancer cells disrupt the integrity of blood vessels during invasion¹⁹⁸. If coagulation were allowed to proceed under these circumstances, it would sequester migrating cancer cells. Therefore, inhibition of the extrinsic coagulation pathway could permit widespread cancer dissemination. The inhibited coagulation in ALDH^{high} cells along with the increased capacity for invasion further supports the conclusion that ALDH^{high} cells represent the population that initiates metastasis.

73

Figure 4.19: SKOV3 Coagulation System

Pathway analysis of microarray data. Data is presented as ALDH^{high} taxol-resistant SKOV3 cells relative to ALDH^{low} SKOV3 cells. Genes shaded in yellow were upregulated and genes shaded in blue were downregulated.

Inconsistent Expression of Previously Reported Ovarian Cancer Stem Cell Markers in ALDH^{high} Cells

In addition to ALDH1, several different markers have been proposed to enrich for ovarian cancer stem cells, including CD24, CD44, KIT and CD133. However, most studies only examined one marker. Because of this, it is not known if these markers identify the same cell population. Gene expression analysis of ALDH^{high} and ALDH^{low} cells allowed for examination of alternative ovarian cancer stem cell makers to determine coexpression. By assessing two distinct ovarian cancer subtypes, those makers with consistent coexpression could be identified.

While CD24 has been proposed as an ovarian cancer stem cell marker, disagreements exist concerning whether ovarian cancer stem cells express it to a greater or lesser degree than differentiated cells^{46, 59}. ALDH^{high} taxol-resistant SKOV3 cells exhibited substantial downregulation of CD24 relative to ALDH^{low} SKOV3 cells (Table 4.5, pg. 108). ALDH^{high} FNAR-C1 cells also showed downregulation of CD24, but to a lesser degree than in SKOV3 cells (Table 4.5, pg. 108). Therefore, ovarian cancer stem cells may express lower levels of CD24 than differentiated cells. However, all populations expressed considerable levels of CD24, potentially limiting its usefulness as a marker for isolation.

High expression of CD44 has been reported to enrich for ovarian cancer stem cells^{28, 29}. In opposition to these reports, ALDH^{high} FNAR-C1 cells exhibited substantial downregulation of CD44 relative to ALDH^{low} FNAR-C1 cells (Table 4.5,

pg. 108). However, there was no difference in CD44 expression between ALDH^{high} taxol-resistant SKOV3 cells and ALDH^{low} SKOV3 cells (Table 4.5, pg. 108). Additionally, both SKOV3 populations showed very high levels of expression. While these results contradict previous reports using CD44 positivity to isolate ovarian cancer stem cells, there are reports of tumorigenic ovarian cancer cells lacking CD44 expression^{36, 37}. The data presented here indicates variable expression of CD44 in ALDH^{high} cells, which challenges the use of CD44 as a universal ovarian cancer stem cell marker.

Published reports of ovarian cancer stem cells demonstrate stark variability in KIT expression, which is reflected in this study^{25, 29, 34, 61}. In FNAR-C1 cells, KIT expression was too low for differences to be reliably detected by microarray. PCR data showed that KIT expression was largely confined to the ALDH^{high} population (Table 4.5, pg. 108). ALDH^{high} taxol-resistant SKOV3 cells exhibited the opposite pattern with expression of KIT only reliably detected in ALDH^{low} SKOV3 cells (Table 4.5, pg. 108). In conjunction with previously published results, these findings indicate dynamic expression of KIT in ovarian cancer stem cells.

Ovarian cancer stem cells have been isolated based on CD133 positivity^{49, 55}. CD133 expression was too low to be reliably detected in FNAR-C1 cells using microarray analysis. PCR analysis showed possible downregulation of CD133 in ALDH^{high} FNAR-C1 cells (Table 4.5, pg. 108). CD133 was undetectable in the ALDH^{high} population but appeared to be expressed at a very low level in the ALDH^{low}

fraction. In ALDH^{high} taxol-resistant SKOV3 and ALDH^{low} SKOV3 cells, CD133 expression was too low for reliable detection by either assay (Table 4.5, pg. 108). Therefore, ALDH^{high} cells do not express higher levels of CD133. Furthermore, none of the tested populations displayed robust expression of CD133. This is consistent with findings of CD133 expression in only 30% of ovarian tumors, which limits the potential of CD133 for isolation of ovarian cancer stem cells⁵⁷.

Multiple markers of ovarian cancer stem cells have been proposed and each marker has been shown to identify a population of ovarian cancer cells with stem cell properties. Published studies have generally only examined one marker. This does not allow for comparison of the different markers, and so it is not known if these markers identify the same cell population. The data presented here suggests overlap between cells with high expression of ALDH1 and decreased expression of CD24. The remaining markers (CD44, KIT and CD133) do not exhibit consistent differential expression in ALDH^{high} cells indicating that these markers identify different cell populations than ALDH1.

No Consistent Differential Regulation of Hormone Receptors in ALDH^{high} Cells

Steroid hormones and their receptors have been implicated in the pathogenesis of ovarian cancer, and hormone receptor status serves as a prognostic indicator. Therefore, it is important to evaluate differential expression of hormone receptors in ovarian cancer stem cells. Expression of estrogen receptor α (ESR1) was too low to

reliably detect differences by microarray. PCR data indicated downregulation of ESR1 in ALDH^{high} FNAR-C1 cells compared to ALDH^{low} FNAR-C1 cells (Table 4.5, pg. 108). ALDH^{high} taxol-resistant SKOV3 cells, however, exhibited upregulation of ESR1 relative to ALDH^{low} SKOV3 cells (Table 4.5, pg. 108). In FNAR-C1 cells, progesterone receptor (PGR) expression appeared to be predominantly confined to ALDH^{high} cells (Table 4.5, pg. 108). In SKOV3 cells, the opposite pattern was seen. ALDH^{high} taxol-resistant SKOV3 cells did not express detectable levels of PGR, but very low levels of expression were detected in ALDH^{low} SKOV3 cells (Table 4.5, pg. 108). In all populations tested, expression of androgen receptor was too low to reliably detect differences. Overall, no consistent differences in hormone receptor expression were found between ALDH^{high} and ALDH^{low} cells, suggesting no reliable association exists between hormone receptor expression and ovarian cancer stem cells.

Gonadotropins have been proposed to play a role in the progression of ovarian cancer, and therapies targeting gonadotropin receptors have been tested. Therefore, the expression of gonadotropin receptors in ovarian cancer stem cells may be relevant to therapeutics. Modest expression of follicle stimulating hormone receptor (FSHR) was measured in ALDH^{high} and ALDH^{low} FNAR-C1 cells by microarray (Table 4.5, pg. 108). FSHR could not be detected by PCR, but the clear expression by microarray suggests that this is likely a technical rather than biological phenomenon (Table 4.5, pg. 108). ALDH^{high} taxol-resistant SKOV3 and ALDH^{low} SKOV3 cells did not appear to express FSHR when measured by microarray (Table 4.5, pg. 108). Luteinizing

hormone/choriogonadotropin receptor (LHCGR) did not appear to be expressed in any population tested (Table 4.5, pg. 108). Overall, gonadotropin receptors do not appear to be consistently expressed in ALDH^{high} cells, which could have important implications for gonadotropin receptor targeted therapies.

Although her-2/neu and CA125 are not hormone receptors, their prognostic importance in ovarian cancer necessitates evaluation of expression levels in ovarian cancer stem cells. High levels of her-2/neu (ERBB2) expression were detected in all populations tested, but no reliable differences were found between ALDH^{high} and ALDH^{low} cells (Table 4.5, pg. 108). Therefore, ERBB2 does not appear to be consistently differentially regulated in ALDH^{high} ovarian cancer cells. Modest expression of CA125 (MUC16) was detected in all populations studied. ALDH^{high} FNAR-C1 cells showed upregulation of MUC16 relative to ALDH^{low} FNAR-C1 cells (Table 4.5, pg. 108). In contrast, no differences were seen between ALDH^{high} taxol-resistant SKOV3 cells and ALDH^{low} SKOV3 cells (Table 4.5, pg. 108). This indicates consistent expression of MUC16 in ovarian cancer stem cells.

Upregulation of MDR1, But Not Other ABC Transporters, in ALDH^{high} Cells

Increased expression of ATP-binding cassette (ABC) transporters leads to resistance to a wide array of drugs, possibly causing multi-drug resistance in stem cells¹⁹⁹. The only ABC transporter that showed strong upregulation in ALDH^{high} cells of both models was the multidrug resistance protein 1 (MDR1), which is designated ABCB1 in humans and ABCB1B in rats (Table 4.2, pg. 98). Resistance to taxol

primarily results from increased expression of MDR1. Because the human model compares taxol-resistant to taxol-sensitive SKOV3 cells, upregulation of MDR1 may be associated with the acquisition of taxol resistance. Members of the multidrug resistance-associated protein subfamily (ABCC_) also induce multi-drug resistance. In ALDH^{high} and ALDH^{low} FNAR-C1 cells, high expression of ABCC1 was seen with the highest expression in ALDH^{low} cells (Table 4.5, pg. 108). In contrast, similar levels of modest ABCC1 expression were detected in ALDH^{high} taxol-resistant SKOV3 cells and ALDH^{low} SKOV3 cells (Table 4.5, pg. 108). ABCC3 was upregulated in ALDH^{high} taxol-resistant SKOV3 cells but was still highly expressed in both populations (Table 4.5, pg. 108). Conversely, both populations of FNAR-C1 cells showed similarly low levels of ABCC3 expression (Table 4.5, pg. 108). Side population is one proposed method to enrich for stem cells and is commonly attributed to ABCG2 expression^{38, 39}. Similarly high levels of ABCG2 expression were seen in ALDH^{high} and ALDH^{low} FNAR-C1 cells with no apparent difference between the two populations (Table 4.5, pg. 108). However, ABCG2 was found to be upregulated in ALDH^{high} taxol-resistant SKOV3 cells relative to ALDH^{low} SKOV3 cells (Table 4.5, pg. 108). Although expression of ABCG2 varied in ALDH^{low} cells, consistent expression was seen in the ALDH^{high} population. No other ABC transporters associated with a stem cell phenotype or drug resistance were differentially regulated in either model. Overall, these data suggest that expression of ABC transporters may

not be consistently differentially regulated between ovarian cancer stem cells and their differentiated counterparts.

Telomerase Is Not Upregulated in ALDH^{high} Cells

Cells that undergo repeated cell division must maintain telomere length. Accordingly, elevated telomerase activity has been reported in a variety of cancer stem cells, and so expression of telomerase genes was examined²⁰⁰⁻²⁰². Both ALDH^{high} and ALDH^{low} populations of FNAR-C1 cells showed comparably modest levels of TERC expression (Table 4.5, pg. 108). Modest expression of TERC was also detected in ALDH^{high} taxol-resistant SKOV3 and ALDH^{low} SKOV3 cells, but with slight upregulation in the ALDH^{high} population (Table 4.5, pg. 108). Relative to expression levels of TERC, FNAR-C1 cells expressed higher levels of TERT, but SKOV3 cells expressed lower levels of TERT. TERT was not differentially expressed in ALDH^{high} FNAR-C1 compared to ALDH^{low} FNAR-C1 cells (Table 4.5, pg. 108). In contrast, TERT was downregulated in ALDH^{high} taxol-resistant SKOV3 cells versus ALDH^{low} SKOV3 cells (Table 4.5, pg. 108). All populations tested exhibited very high expression of DKC1 with possible slight downregulation in ALDH^{high} cells compared to ALDH^{low} cells in both models (Table 4.5, pg. 108). FNAR-C1 cells expressed high levels of TEP1 with no apparent differences between ALDH^{high} and ALDH^{low} populations (Table 4.5, pg. 108). However, SKOV3 cells showed low expression of TEP1 with downregulation in ALDH^{high} taxol-resistant SKOV3 cells. Overall, no consistent upregulation of telomerase genes was observed in ALDH^{high} cells.

Additionally, the specific telomerase genes displayed highly variable levels of expression within the same populations. This suggests that telomerase activity is not responsible for telomere maintenance in these models.

Developmental Pathways Are Not Consistently Active In ALDH^{high} Cells

Developmental pathways not only regulate embryonic development, but various reports suggest that they also play an important role in ovarian cancer stem cells. Proliferation of ovarian cancer stem cells depends on NFκB signaling²⁰³. The Wnt/β-catenin pathway regulates tumor-initiating capacity and chemoresistance in ovarian cancer stem cells^{204, 205}. Ovarian cancer stem cell survival involves Notch signaling³⁵. Although no data specific to ovarian cancer stem cells exists at this time, Hedgehog signaling has been reported in cancer stem cells and chemoresistant ovarian cancer cells^{54, 206}. Because of the reported importance of developmental pathways in ovarian cancer stem cells, gene expression patterns for the NFκB, Wnt/β-catenin, Notch and Hedgehog pathways were examined in ALDH^{high} cells.

Analysis of the NFκB pathway revealed upregulation of many genes in ALDH^{high} FNAR-C1 cells relative to ALDH^{low} FNAR-C1 cells (Figure 4.20). Receptors often serve as a primary level of pathway regulation. Accordingly, ALDH^{high} cells expressed higher levels of several NFκB pathway receptors. Toll-like receptor 3, which activates the NFκB pathway in response to double-stranded RNA, showed 2.51-fold upregulation²⁰⁷. Activating growth factor receptors also exhibited

upregulation, including: fibroblast growth factor receptors 1 and 2 (FGFR1: 3.82-fold, 24.101-fold by PCR; FGFR2: 22.67-fold, 33.065-fold by PCR), fms-related tyrosine kinase 1 (3.13-fold), and growth hormone receptor (4.65-fold)²⁰⁸⁻²¹⁰. In addition to receptors, intracellular kinases regulate pathway activity. ALDH^{high} cells showed 4.18-fold upregulation of mitogen-activated protein kinase kinase 6, which triggers a signaling cascade that activates NFκB²¹¹. Finally, ALDH^{high} cells displayed 2.99-fold (3.553-fold by PCR) upregulation of a component of the NFκB complex, RELA²¹². Although not differentially regulated, both ALDH^{high} and ALDH^{low} FNAR-C1 cells strongly expressed NFκB. Overall, upregulation of receptors, an activating kinase and a component of the NFκB complex indicates increased NFκB pathway activity in ALDH^{high} FNAR-C1 cells.

Conversely, ALDH^{high} taxol-resistant SKOV3 cells showed downregulation of the NFκB pathway compared to ALDH^{low} SKOV3 cells (Figure 4.21). Differential expression of receptors served as the primary level of regulation. TNFRSF11B and interleukin 1 receptor type II (IL1R2) are decoy receptors that lack intracellular signaling motifs, thereby inhibiting pathway activation^{213, 214}. ALDH^{high} cells displayed 2.09-fold upregulation of TNFRSF11B and 2.40-fold upregulation of IL1R2. Furthermore, the activating receptor TGFBR2 exhibited 2.69-fold (12.987-fold by PCR) downregulation²¹⁵. The observed downregulation of a signaling receptor and upregulation of decoy receptors suggests reduced activity of the NFκB pathway in ALDH^{high} taxol-resistant SKOV3 cells.

[illegible]

84

Figure 4.21: SKOV3 NFκB Signaling

Pathway analysis of microarray data. Data is presented as ALDH^{high} taxol-resistant SKOV3 cells relative to ALDH^{low} SKOV3 cells. Genes shaded in yellow were upregulated and genes shaded in blue were downregulated.

The Wnt/ β -catenin pathway exhibited substantial differential regulation in ALDH^{high} FNAR-C1 cells relative to ALDH^{low} FNAR-C1 cells (Figure 4.22). ALDH^{high} cells showed upregulation of multiple WNT genes, including: WNT2B (93.69-fold, 581.598-fold by PCR), WNT4 (10.79-fold, 18.296-fold by PCR), WNT10A (2.56-fold), and WNT11 (10.75-fold, 15.722-fold by PCR). Although secreted WNT proteins can act in an autocrine or paracrine manner, upregulation of intracellular pathway components in ALDH^{high} cells suggests increased Wnt/ β -catenin activity in this population. MARK2 promotes nuclear translocation of β -catenin and exhibited 4.29-fold upregulation (5.212-fold by PCR) in ALDH^{high} cells²¹⁶. However, observation of nuclear β -catenin in unsorted cells cultured in differentiation medium suggests that nuclear β -catenin may not be restricted to the ALDH^{high} population (Figure 2.4). Transcription of β -catenin target genes requires the LEF/TCF complex in addition to nuclear β -catenin²¹⁷. ALDH^{high} cells displayed 3.31-fold upregulation (88.626-fold by PCR) of LEF1 and 4.20-fold upregulation (6.754-fold by PCR) of TCF7L1. Additionally, ALDH^{low} cells did not express detectable levels of LEF1. This implies that transcription of β -catenin target genes can only take place in ALDH^{high} cells. Therefore, ALDH^{high} FNAR-C1 cells have increased Wnt/ β -catenin pathway activity versus ALDH^{low} cells.

Figure 4.22: FNAR-C1 Wnt/ β -Catenin Signaling

Pathway analysis of microarray data. Data is presented as ALDH^{high} FNAR-C1 cells relative to ALDH^{low} FNAR-C1 cells. Genes shaded in yellow were upregulated and genes shaded in blue were downregulated.

Figure 4.23: SKOV3 Wnt/ β -Catenin Signaling

Pathway analysis of microarray data. Data is presented as ALDH^{high} taxol-resistant SKOV3 cells relative to ALDH^{low} SKOV3 cells. Genes shaded in yellow were upregulated and genes shaded in blue were downregulated.

In contrast, ALDH^{high} taxol-resistant SKOV3 cells showed downregulation of the Wnt/ β -catenin pathway relative to ALDH^{low} SKOV3 cells (Figure 4.23). ALDH^{high} cells exhibited 1.63-fold downregulation (2.519-fold by PCR) of β -catenin (CTNNB1). In addition to downregulation of this crucial transcriptional coregulator, frizzled family receptor 2 (FZD2), the predominant frizzled receptor expressed in these cells, displayed 1.62-fold downregulation in ALDH^{high} cells. Additional reduction of pathway activity in ALDH^{high} cells was suggested by 2.67-fold upregulation of the inhibitor SOX17 and 1.60-fold downregulation of the activator APPL2^{218, 219}. Based on downregulation of the preponderant receptor, downregulation of β -catenin, and differential regulation of genes that modulate pathway activity, the Wnt/ β -catenin pathway appears to be less active in ALDH^{high} taxol-resistant SKOV3 cells than in ALDH^{low} SKOV3 cells.

Although few genes of the Notch pathway were differentially regulated in ALDH^{high} FNAR-C1 cells compared to ALDH^{low} FNAR-C1 cells, those that were differentially expressed serve as important regulators of pathway activity (Figure 4.24). ALDH^{high} cells exhibited downregulation of the Notch ligands jagged 1 (JAG1, 1.85-fold) and jagged 2 (JAG2, 6.14-fold), which would primarily impact signaling in adjacent cells. However, the endocytosis of Notch ligands bound to cleaved Notch also alters signaling in the ligand-expressing cell²²⁰. Manic fringe (MFNG) inhibits jagged 1 activation of Notch signaling and showed 3.66-fold upregulation in ALDH^{high} cells²²¹. Overall, ALDH^{high} FNAR-C1 cells displayed differential regulation of genes

that suggests reduced Notch signaling, but this effect may not be limited to the ALDH^{high} population.

Differential regulation of Notch pathway genes in ALDH^{high} taxol-resistant SKOV3 cells versus ALDH^{low} SKOV3 cells suggests altered Notch signaling (Figure 4.25). The only intracellular pathway component to exhibit differential regulation was nicastrin (NCSTN), which is a component of the γ -secretase complex. γ -Secretase cleaves the intracellular domain of Notch to permit signaling²²². Although nicastrin showed 1.52-fold downregulation in ALDH^{high} cells, the gene was still highly expressed in both ALDH^{high} and ALDH^{low} cells, and the other known components of γ -secretase were expressed at similar levels in both populations. Therefore, γ -secretase is likely active in both populations. Altered Notch signaling appeared to be primarily due to 2.12-fold downregulation of lunatic fringe (LFNG) in ALDH^{high} cells. Lunatic fringe inhibits jagged 1 signaling through Notch 1, and so downregulation would increase Notch signaling²²³. Differential regulation of genes in ALDH^{high} taxol-resistant SKOV3 cells suggests increased Notch signaling, however this altered signaling may impact other cell populations as well.

Figure 4.24: FNAR-C1 Notch Signaling

Pathway analysis of microarray data. Data is presented as ALDH^{high} FNAR-C1 cells relative to ALDH^{low} FNAR-C1 cells. Genes shaded in yellow were upregulated and genes shaded in blue were downregulated.

Figure 4.25: SKOV3 Notch Signaling

Pathway analysis of microarray data. Data is presented as ALDH^{high} taxol-resistant SKOV3 cells relative to ALDH^{low} SKOV3 cells. Genes shaded in yellow were upregulated and genes shaded in blue were downregulated.

The data presented here indicates inconsistent developmental pathway activity in ovarian cancer stem cells from different sources. ALDH^{high} FNAR-C1 cells displayed upregulation of the NFκB and Wnt/β-catenin pathways but downregulation of Notch signaling. ALDH^{high} taxol-resistant SKOV3 cells demonstrated the opposite pattern with upregulated Notch signaling but downregulated NFκB and Wnt/β-catenin pathways. The only consistency between the two models was that neither model exhibited differential regulation of the Hedgehog pathway. While this data indicates a role for developmental pathways in ovarian cancer stem cells, their significance is not consistent.

Potential Therapeutic Targets to Eliminate ALDH^{high} Cells

The primary purpose of studying ovarian cancer stem cells was to identify potential therapies. If the cancer stem cell hypothesis is accurate, eliminating ovarian cancer stem cells should lead to durable remission for patients. Microarray data identified gene expression profiles in ALDH^{high} cells that could be exploited for cancer stem cell-targeted therapy. These potential therapeutic targets include the mTOR pathway, her-2/neu, CD47 and FGF18.

Differential gene expression of ALDH^{high} cells from both models indicates increased mTOR signaling. Figure 4.26 shows the mTOR pathway in ALDH^{high} FNAR-C1 cells compared to ALDH^{low} FNAR-C1 cells. The mTOR pathway in ALDH^{high} taxol-resistant SKOV3 cells relative to ALDH^{low} SKOV3 cells is displayed in Figure 4.27. The primary mechanism of increased mTOR signaling involved

modulation of the tuberous sclerosis complex (TSC), which inhibits mTOR activation through RHEB²²⁴. ALDH^{high} FNAR-C1 cells inhibited TSC complex activity through 4.61-fold upregulation of insulin receptor substrate 1 (IRS1)²²⁵. Inhibition of the TSC complex in ALDH^{high} taxol-resistant SKOV3 cells was achieved with 1.58-fold upregulation of PI3K²²⁶. ALDH^{high} cells of both models additionally blocked TSC inhibition of the mTOR pathway through upregulation of RPS6KB2 (FNAR-C1: 3.23-fold; SKOV3: 1.55-fold)²²⁷. Not shown in the pathway analysis is ras-related GTP binding D (RRAGD), which stimulates the mTOR pathway²²⁸. ALDH^{high} cells from both models exhibited upregulation of RRAGD (Table 4.2, pg. 98). The increased activity of the mTOR pathway in ALDH^{high} cells of both models suggests that inhibition of mTOR signaling could eliminate ovarian cancer stem cells. The mTOR inhibitor rapamycin has been administered clinically for more than a decade. Because the clinical safety of rapamycin is well established, clinical testing for the treatment of ovarian cancer could proceed rapidly.

Ovarian cancer specimens commonly express her-2/neu (ERBB2)²²⁹. Accordingly, expression of ERBB2 was detected in both models. FNAR-C1 cells showed strong expression in both ALDH^{high} and ALDH^{low} fractions (Table 4.5, pg. 108). SKOV3 cells expressed ERBB2 at a sufficiently high level as to suggest overexpression. Furthermore, ALDH^{high} taxol-resistant SKOV3 cells displayed a slight, but consistent, upregulation of ERBB2 relative to ALDH^{low} SKOV3 cells (Table 4.5, pg. 108). Because both ALDH^{high} populations expressed ERBB2, ERBB2-

targeted therapy could potentially eliminate ovarian cancer stem cells in patients with detectable expression. Several drugs targeting ERBB2 are currently clinically available, which would reduce the time necessary for clinical testing.

Figure 4.26: FNAR-C1 mTOR Signaling

Pathway analysis of microarray data. Data is presented as ALDH^{high} FNAR-C1 cells relative to ALDH^{low} FNAR-C1 cells. Genes shaded in yellow were upregulated and genes shaded in blue were downregulated.

Figure 4.27: SKOV3 mTOR Signaling

Pathway analysis of microarray data. Data is presented as ALDH^{high} taxol-resistant SKOV3 cells relative to ALDH^{low} SKOV3 cells. Genes shaded in yellow were upregulated and genes shaded in blue were downregulated.

CD47 prevents phagocytosis by macrophages and is highly expressed in normal and malignant stem cells^{230, 231}. ALDH^{high} cells of both models expressed higher levels of CD47 than their ALDH^{low} counterparts (Table 4.2, pg. 99).

Accordingly, therapy targeting CD47 could potentially eradicate ovarian cancer stem cells. Preclinical studies suggest that CD47-specific antibodies could effectively treat a broad range of cancers, including ovarian cancer²³². Should this treatment strategy proceed to clinical use, it may successfully eliminate all populations of ovarian cancer cells.

Both ALDH^{high} populations exhibited upregulation of fibroblast growth factor 18 versus their ALDH^{low} counterparts (FGF18; Table 4.2, pg. 98). FGF18 primarily signals through fibroblast growth factor receptor 3 (FGFR3), which was expressed in all populations tested²³³. Therefore, FGF18 signaling may serve an important role in all populations of ovarian cancer cells, and FGFR3 inhibition might successfully treat ovarian cancer stem cells. Encouragingly, several small molecule inhibitors of FGFR3 are in clinical development for cancer treatment.

This table lists members of gene families with similar function that are consistently differentially regulated in both models by microarray. Fold change values from microarray analysis are presented and fold-change values from PCR analysis are shown in parenthesis. Arrows denote direction of change when fold-change values cannot be calculated because one sample is undetectable by PCR. ** Denotes genes undetectable by PCR in both samples. FNAR-C1 data is presented as ALDH^{high} FNAR-C1 cells versus ALDH^{low} FNAR-C1 cells. SKOV3 data is presented as ALDH^{high} taxol-resistant SKOV3 cells versus ALDH^{low} SKOV3 cells.

TEP1	-1.369	-1.179	1.014	-2.421

This table lists genes important in cancer stem cells or ovarian cancer along with fold-change values from microarray and PCR. FNAR-C1 data is presented as ALDH^{high} FNAR-C1 cells versus ALDH^{low} FNAR-C1 cells. SKOV3 data is presented as ALDH^{high} taxol-resistant SKOV3 cells versus ALDH^{low} SKOV3 cells. Arrows signify direction of change when gene was undetectable in one sample. ** Signifies that the gene was not detectable in either sample. Empty cells signify that the gene was not tested with that assay.

5 Discussion

ALDH^{high} Cells Represent Ovarian Cancer Stem Cells

The cancer stem cell hypothesis proposes that, although altered, the differentiation hierarchy of malignancies remains intact with rare stem cell populations giving rise to the differentiated progeny that comprise the bulk of the tumor. Cancer stem cells have been identified in many cancers, and these cells have been proposed to initiate metastases and relapse. This project identified putative ovarian cancer stem cells based on high aldehyde dehydrogenase 1 (ALDH1) activity in two models of ovarian cancer. The first model was the FNAR-C1 rat model of ovarian cancer, which most closely resembles an endometrioid carcinoma. One

benefit of this model is that it originated from a spontaneous tumor and therefore does not have artificial genetic manipulation. It can also be readily transplanted into immunocompetent Lewis rats, which may be more representative than xenografts into immunodeficient mice. Although the endometrioid subtype is a less aggressive subtype, it would be ideal to identify a marker that isolates ovarian cancer stem cells in all ovarian cancer subtypes²³⁴.

In order to control for species or subtype differences, the human SKOV3 cell line was also studied. The initial report of the SKOV3 cell line did not describe the subtype²³⁵. Subsequent analyses described SKOV3 cells as both serous and clear cell subtypes^{76, 77}. The serous subtype is the most common form of ovarian cancer, representing approximately 70% of cases²³⁶. Meanwhile, only 10% of ovarian cancer cases are of the clear cell subtype²³⁶. When stratified by stage, serous and clear cell subtypes have similar prognoses; however, patients with the serous subtype are much less likely to present in stage I than those with the clear cell subtype^{236, 237}. Despite the uncertain histological subtype represented by SKOV3 cells, this model is distinct from the endometrioid subtype of FNAR-C1 cells. Therefore, the use of these two models should allow for identification of ovarian cancer stem cells across all subtypes.

High ALDH1 activity (ALDH^{high}) is strongly associated with stem cells and chemoresistant cells^{62, 238, 239}. Additionally, multiple types of cancer stem cells have been reported to possess high ALDH1 enzyme activity^{20, 63-65, 67, 74}. For these reasons, ovarian cancer cells were isolated based on ALDH1 activity and examined for stem

cell characteristics. Cells cultured in medium containing serum (referred to as differentiation medium) lacked a distinct ALDH^{high} population (Figure 4.1A, C). In order to study ALDH^{high} cells, it was necessary to culture cells in medium that supported the expansion of undifferentiated cells (KnockOut medium). FNAR-C1 cells maintained in KnockOut medium possessed a distinct ALDH^{high} population (Figure 4.1B). SKOV3 cells, on the other hand, remained ALDH^{low} (data not shown). Examination of a taxol-resistant SKOV3 subline showed a prominent ALDH^{high} population (Figure 4.1D). To further expand this population, taxol-resistant SKOV3 cells were cultured in KnockOut medium (Figure 4.1E). Using these conditions permitted the comparison of ALDH^{high} and ALDH^{low} populations from both models.

A concern of comparing cells from distinct culture conditions is that differences between the two populations may be due to biology or the differing media. However, less than ten percent of differentially regulated genes were consistent between the two models. Because so few genes were consistently differentially regulated, the observed differences between ALDH^{high} and ALDH^{low} cells is likely to be due to the underlying biology of the cells. An additional concern is comparing taxol-resistant to taxol-sensitive SKOV3 cells, as this could identify differences due to drug resistance rather than a stem cell phenotype. To control for this, microarray data from the SKOV3 model was compared to the FNAR-C1 model, which had not undergone drug selection. Only those differences that were consistent between the two models were presented thus eliminating differences due to drug resistance alone.

Moreover, taxol-resistant SKOV3 cells displayed resistance to additional drugs with different mechanisms of resistance, which makes it unlikely that the taxol resistance per se was responsible for the observed biological differences

With the populations identified, it became possible to test the hypothesis that cells with high ALDH1 activity have a stem cell phenotype. The first category of stem cell properties examined was growth characteristics, which included nonadherent growth, relative quiescence and lacking contact inhibition. ALDH^{high} cells displayed an absence of contact inhibition with the formation of nodules, which were not seen in ALDH^{low} cells (Figure 4.2A). The capacity for nonadherent growth, as shown through the formation of spheroids, was also restricted to the ALDH^{high} population (Figure 4.2B, C). Gene expression analysis showed a block at the G1/S checkpoint in ALDH^{high} cells (Figures 4.6 and 4.7). Because of this, the ALDH^{high} population contained fewer dividing cells than the ALDH^{low} population (Figure 4.5) resulting in a slower growth rate (Figure 4.4). Taken together, ALDH^{high} cells were more quiescent than their ALDH^{low} counterparts. Overall, ALDH^{high} cells possessed growth characteristics consistent with a stem cell phenotype.

Cancer stem cells are hypothesized to possess additional biological features, such as smaller size, the ability to regenerate the phenotypic diversity of the tumor, self-renewal, increased tumorigenicity, and drug resistance¹²⁷⁻¹³³. ALDH^{high} cells were smaller in size than their ALDH^{low} counterparts, which may be due to their relative quiescence (Figure 4.3). ALDH^{high} cells were the only population able to produce

both ALDH^{high} and ALDH^{low} cells, thus regenerating the phenotypic diversity of the cell line (Figures 4.8 and 4.9). This indicates the loss of ALDH1 activity concurrent with differentiation. The expansion of ALDH^{high} cells additionally suggests the capacity for self-renewal. Tumorigenicity was confined to the ALDH^{high} population (Table 4.1). Exposure to drugs with different mechanisms of action and resistance revealed multi-drug resistance in ALDH^{high} cells (Figure 4.10)^{144, 240-247}. Additionally, culture with taxol increased the percentage of ALDH^{high} cells (Figure 4.11). Therefore, ALDH^{high} cells display biological characteristics of stem cells.

Gene expression patterns may also indicate a stem cell phenotype (Figures 4.12 to 4.15). ALDH^{high} cells expressed higher levels of genes commonly restricted to stem cells and lower levels of genes associated with differentiation. Differential gene expression suggested the capacity for self-renewal in ALDH^{high} cells. Genes associated with the maintenance of pluripotency were upregulated in ALDH^{high} cells as were genes involved in quiescence. ALDH^{high} cells also exhibited upregulation of genes important for stem or progenitor cell proliferation. Thus, differential gene expression in ALDH^{high} cells further supports the conclusion that this population represents ovarian cancer stem cells.

Since ALDH^{high} cells displayed numerous cancer stem cell properties, analysis of ALDH^{high} cells may reveal properties of ovarian cancer stem cells. Because of its comprehensive nature, microarray analysis was employed to compare ALDH^{high} and ALDH^{low} cells, and real-time qRT-PCR of individual genes was performed to validate

the findings. By better understanding the biology of ovarian cancer stem cells, targeted therapeutics can be developed in order to improve patient outcomes.

ALDH^{high} Cells Represent a Biologically Distinct Population

Differential gene expression indicated increased tight junction signaling in ALDH^{high} cells (Figures 4.16 and 4.17). Transmembrane components of tight junctions were upregulated as well as intracellular signaling molecules. The increased tendency of ALDH^{high} cells to form tight junctions may explain the observed formation of spheroids by these cells (Figure 4.2B, C)^{248, 249}. Decreased cell cycle progression appears to be one result of these junctions. Junctional adhesion molecule 3 (JAM3) binds cingulin, which inhibits cell cycle progression by binding to Rho/Rac guanine nucleotide exchange factor 2 (ARHGEF2)^{250, 251}. Both models showed differential regulation of the components of these interactions. ALDH^{high} FNAR-C1 cells expressed increased levels of JAM3. Conversely, ALDH^{high} taxol-resistant SKOV3 cells exhibited upregulation of cingulin and downregulation of ARHGEF2. This signaling interaction may provide a mechanism for contact inhibition. Intriguingly, ALDH^{high} cells in nodules and spheroids continue to proliferate, albeit at a very slow rate, suggesting that some Aldefluor high cells escape this growth inhibition.

Ovarian cancer stem cells have been proposed to be responsible for invasion and metastasis. Differential gene expression in ALDH^{high} cells provides support for this hypothesis (Table 4.4). ALDH^{high} cells showed downregulation of multiple tumor

suppressor genes, indicating a more malignant phenotype with increased proliferation, migration and invasion^{173, 177, 252-256}. In addition to the loss of tumor suppressor genes, ALDH^{high} cells exhibited upregulation of genes contributing to invasion, including enzymes responsible for extracellular matrix degradation. Not only were degradation enzymes upregulated, but inhibitors of degradation were also downregulated. Further permitting invasion, ALDH^{high} cells downregulated basement membrane deposition. Taken together, ALDH^{high} cells demonstrated an increased capacity for migration and invasion compared to ALDH^{low} cells. One route for dissemination of cancer cells is the vascular system. Activation of the extrinsic pathway of the coagulation cascade could potentially inhibit this migration. Tissue factor pathway inhibitor (TFPI) inhibits the initiation of the extrinsic pathway and was upregulated in ALDH^{high} cells (Table 4.2, Figure 4.18 and Figure 4.19). Combined with increased invasiveness, the prevention of coagulation observed in ALDH^{high} cells indicates an ability to enter the blood and lead to distant metastases. Overall, differential gene expression in ALDH^{high} cells supports the hypothesis that ovarian cancer stem cells are more malignant than their differentiated counterparts and represent the cell population capable of migration, invasion and metastasis.

ALDH^{high} Cells Have Inconsistent Expression of Previously Reported Ovarian Cancer Stem Cell Markers

In addition to high ALDH1 activity, other markers have been reported to identify ovarian cancer stem cells, including CD24, CD44, KIT and CD133. Because

most studies only examine one marker, it is not known if these varied markers identify the same cell population. This project permitted the evaluation of marker expression levels in ALDH^{high} and ALDH^{low} cells from two different ovarian cancer subtypes. CD24 was the only marker to show consistent differential expression between the two models (Table 4.5). Previous reports disagree as to whether ovarian cancer stem cells express CD24 to a greater or lesser degree than their differentiated progeny^{46, 59}. Data presented here indicated reduced CD24 expression in ovarian cancer stem cells. However, all populations showed strong expression of CD24, potentially limiting the usefulness of this marker for isolation. Variable expression of CD44 and KIT have been reported for putative ovarian cancer stem cells and this study confirmed previously reported variability^{29, 35, 37, 61}. CD44 was downregulated in ALDH^{high} FNAR-C1 cells but unchanged in ALDH^{high} taxol-resistant SKOV3 cells. KIT was upregulated in ALDH^{high} FNAR-C1 cells but downregulated in ALDH^{high} taxol-resistant SKOV3 cells. Despite reports of CD133 expression on ovarian cancer stem cells, only 30-70% of ovarian cancer specimens express detectable levels of CD133^{55, 56}. Expression of CD133 could not be reliably detected in any population tested. Therefore, the only previously reported ovarian cancer stem cell marker to be consistently differentially regulated in ALDH^{high} cells was CD24.

The differentiation hierarchy of normal solid tissues is poorly understood, which complicates studies of cancer stem cells in solid tumors. The reason for such varied reports of ovarian cancer stem cell markers is unclear. It is possible that

differentiation proceeds through several stages and each marker identifies a particular stage. Furthermore, ovarian cancer is a collection of diseases with different subtypes, and some markers may be subtype-specific. This project benefits from the study of two distinct subtypes to control for this possibility. Alternatively, heterogeneity between patients may yield inconsistent results. Further study is necessary to distinguish between the potential explanations for marker variability.

No Consistent Differential Regulation of Hormone Receptors in ALDH^{high} Cells

Steroid hormones are often used as prognostic indicators in ovarian cancer, and hormone therapy has been proposed as a treatment strategy. Therefore, expression of hormone receptors in ovarian cancer stem cells could have implications for clinical evaluation and treatment. Estrogen receptor α (ESR1) was differentially regulated in both models, but in opposite directions (Table 4.5). Although expression was low overall, both ALDH^{high} populations expressed detectable levels of ESR1. This indicates variability in ESR1 expression in ovarian cancer stem cells relative to differentiated cells. However, ovarian cancer stem cells likely express ESR1 at sufficient levels for hormone therapy to be effective. Like ESR1, progesterone receptor (PGR) showed conflicting directions of differential regulation in the two models (Table 4.5). In contrast to ESR1, PGR did not show detectable expression in ALDH^{high} taxol-resistant SKOV3 cells suggesting that PGR may not be expressed in all ovarian cancer stem cells. Androgen receptor (AR) expression could not be

reliably detected in any population (Figure 4.5). It is not clear why FNAR-C1 cells showed expression of AR by flow cytometry but not by PCR (Figure 2.3). However, due to upregulation of cytochrome P450 genes that inactivate testosterone, it appears that androgen signaling may not be active in ALDH^{high} cells (CYP3A5 in FNAR-C1 and CYP1B1 in SKOV3; Table 4.4, pg. 104)^{257, 258}. Overall, no consistent differences in hormone receptor expression were seen in ALDH^{high} cells, which indicates variable expression in ovarian cancer stem cells.

Gonadotropin signaling has been implicated in ovarian cancer progression, and gonadotropin-targeted therapies have been proposed. Consequently, gonadotropin receptor expression in ovarian cancer stem cells may have clinical implications. Gonadotropin receptors were infrequently expressed and when expressed did not show differential expression in ALDH^{high} cells. Follicle stimulating hormone receptor (FSHR) was only detected in FNAR-C1 cells (Table 4.5). Luteinizing hormone/choriogonadotropin receptor (LHCGR) was not expressed in any population tested (Table 4.5). Therefore, any therapy targeting gonadotropin receptors would be unlikely to reliably eliminate ovarian cancer stem cells.

Although not hormone or gonadotropin receptors, her-2/neu (ERBB2) and CA125 (MUC16) have implications for ovarian cancer prognosis, necessitating evaluation of their expression in ovarian cancer stem cell. Similarly high levels of ERBB2 expression were detected in ALDH^{high} and ALDH^{low} FNAR-C1 cells (Table 4.5). SKOV3 cells exhibited extremely high levels of ERBB2 expression, suggesting

overexpression. Additionally, ALDH^{high} taxol-resistant SKOV3 cells displayed a slight, but consistent, upregulation of ERBB2 (Table 4.5). Overall, these data suggest that ovarian cancer stem cells consistently express ERBB2 at a similar level as the rest of the tumor. Therefore, any prognostic or therapeutic application for ERBB2 should be unaffected by the presence of ovarian cancer stem cells. CA125 is used clinically to evaluate response to therapy and relapse. FNAR-C1 cells showed modest expression of CA125 with upregulation in ALDH^{high} cells (Table 4.5). Both populations of SKOV3 cells showed consistent, low levels of CA125 expression (Table 4.5). This implies that ovarian cancer stem cells express CA125 and should not interfere with clinical measurements.

Upregulation of MDR1, But Not Other ABC Transporters, In ALDH^{high} Cells

Expression of ATP-binding cassette (ABC) transporters has been proposed as a specific feature of stem cells. The only ABC transporter that was consistently upregulated in ALDH^{high} cells was multidrug resistance protein 1 (MDR1; ABCB1B in rats, ABCB1 in humans; Table 4.2). MDR1 prevents the intracellular accumulation of a broad class of drugs, including taxol, which may account for the observed taxol resistance in ALDH^{high} cells. The multidrug resistance-associated protein subfamily (ABCC_) also causes drug resistance. ABCC1 was downregulated in ALDH^{high} FNAR-C1 cells, but still highly expressed (Table 4.5). SKOV3 cells, on the other hand, showed similar, low levels of ABCC1 expression in both populations (Table 4.5). Conversely, both populations of SKOV3 cells showed high levels of ABCC3

expression, despite upregulation in ALDH^{high} taxol-resistant SKOV3 cells (Table 4.5). Both ALDH^{high} and ALDH^{low} FNAR-C1 cells exhibited modest ABCC3 expression without differential regulation (Table 4.5). Therefore, each model showed strong expression with differential regulation of one member of the multidrug resistance-associated protein subfamily, but neither of these differentially regulated genes were consistent between the two models. The side population phenotype that is often used to enrich for stem cells is attributed to ABCG2 expression. Only ALDH^{high} taxol-resistant SKOV3 cells showed upregulation of ABCG2 (Table 4.5). Similarly high levels of ABCG2 expression were observed in both populations of FNAR-C1 cells (Table 4.5). Accordingly, expression of ABCG2 was consistently found in ALDH^{high} cells, but variable in ALDH^{low} cells. Overall, ovarian cancer stem cells likely express variable levels of ABC transporters and those that are consistent may be clinically relevant.

Telomere Maintenance Is Due To Alternative Lengthening of Telomeres

The gene components of telomerase showed variable levels of expression and inconsistent differential regulation (Table 4.5). This suggests that telomerase is unlikely to be responsible for telomere maintenance in ALDH^{high} cells. Instead, microarray data suggested that alternative lengthening of telomeres might be the mechanism for telomere maintenance (data not shown). Many genes reportedly involved in alternative lengthening of telomeres showed high levels of expression in all populations studied, including the MRN complex (MRE11A, RAD50 and NBN),

proteins that prevent telomere shortening (FEN1, MUS81 and FANCD2), and additional components (TERF1, TERF2, TINF2 and TERF2IP)²⁵⁹⁻²⁶³. ALDH^{high} FNAR-C1 cells showed some upregulation of these genes, including SMC5 (3.226-fold), FEN1 (3.295-fold) and MUS81 (2.058-fold). Functionally though, alternative lengthening of telomeres likely occurs in both ALDH^{high} and ALDH^{low} cells. Because all cells were expanded *in vitro*, all populations required maintenance of telomere length. In order to determine mechanisms of telomere maintenance in ovarian cancer stem cells, primary tumors must be analyzed.

Developmental Pathways Are Not Consistently Active In ALDH^{high} Cells

While the importance of developmental pathways in embryonic development has been well established, recent evidence indicates a role for developmental pathways in normal and malignant adult stem cells as well²⁶⁴⁻²⁷¹. The NFκB, Wnt/β-catenin and Notch pathways showed differential regulation in both models, but with different effects. Differential regulation in ALDH^{high} FNAR-C1 cells indicated active NFκB and Wnt/β-catenin pathways but decreased Notch signaling (Figures 4.20, 4.22 and 4.24). In contrast, ALDH^{high} taxol-resistant SKOV3 cells exhibited increased Notch signaling but downregulated NFκB and Wnt/β-catenin signaling (Figures 4.21, 4.23 and 4.25). Neither model displayed differential regulation of the Hedgehog pathway. This suggests that developmental pathways may have the dual functions of stem cell maintenance or differentiation depending on the context of the cell.

Potential Ovarian Cancer Stem Cell-Targeted Therapy

The ultimate goal of cancer research is to improve patient outcomes. The cancer stem cell hypothesis proposes that eliminating cancer stem cells will lead to durable remission. This study identified potential therapeutic targets on the basis of gene expression, including the mTOR pathway, ERBB2, CD47 and FGF18. Because two distinct subtypes were studied, the results found here are more likely to be representative of all ovarian cancer stem cells.

Of the identified potential therapeutic targets, only the mTOR pathway and CD47 are expected to be specific for ovarian cancer stem cells. ALDH^{high} cells showed increased mTOR activity and upregulation of CD47 compared to ALDH^{low} cells. In contrast, ERBB2 was highly expressed in all populations. Although FGF18 was upregulated in ALDH^{high} cells, the secreted protein could act on either ALDH^{high} or ALDH^{low} cells, both of which express the specific receptor FGFR3. While targeting ERBB2 or FGFR3 would potentially eliminate ovarian cancer stem cells, these treatments would likely also target the differentiated population.

The potential treatment strategies also differ in clinical drug availability. Drugs targeting the mTOR pathway and ERBB2 are already in clinical use, thereby permitting a more rapid application of these treatment schemes. However, ERBB2-targeted therapy has only been used against cells that overexpress ERBB2, and so it remains to be determined if this therapy would also be effective against cells without overexpression. Several FGFR3 inhibitors are in clinical trials, but none has

completed phase 3 trials. Therapy targeting CD47 is still undergoing preclinical testing. Therefore, therapy targeting FGFR3 or CD47 would proceed much more slowly than mTOR- or ERBB2-targeted therapies.

Implications and Future Directions

This project contributes a valuable research model for the study of ovarian cancer. The FNAR-C1 model arose from a spontaneous ovarian tumor, so it lacks artificial genetic manipulation that may not be representative of the human disease. The tumor can be propagated *in vitro*, allowing for more detailed analysis of the cells. The tumor can also be transplanted *in vivo* into immunocompetent animals, permitting investigation of immune system interactions with the cancer. Additionally, recent controversy concerning evaluation of tumorigenicity in immunocompromised animals is circumvented with this model. Finally, the FNAR-C1 model is phenotypically consistent with human endometrioid ovarian cancer, making it a reliable model for this disease. Because the endometrioid subtype is not as common or aggressive as the serous subtype, fewer models of this subtype exist²³⁴. This project provides a model of endometrioid ovarian cancer with the potential to improve understanding of this disease.

In addition to contributing a novel research model, this project further validates the existence of ovarian cancer stem cells as well as the use of high aldehyde dehydrogenase activity as an ovarian cancer stem cell marker. Further research is required to elucidate the reason for the variety of proposed ovarian cancer stem cell

markers. This project begins to resolve this concern by demonstrating inconsistent expression of all markers except CD24. This represents the first analysis of multiple markers in different subtypes and helps to clarify the value of reported markers. Further comparisons remain necessary, ideally in a large cohort of patient samples, in order to fully characterize ovarian cancer stem cell markers.

Furthermore, this project provides the first comprehensive gene expression analysis of ovarian cancer stem cells from two discrete subtypes. This analysis illustrated the variability within ovarian cancer stem cells. In some cases, each achieved the same function but via alternative genes. In other cases, pathways were altered in divergent manners producing diverse properties. Rarely were gene expression differences consistent in both models. By identifying those genes and pathways with consistent expression, potential therapeutic targets were identified. Few studies have proposed targets for ovarian cancer stem cell eradication. Moreover, the few treatments that have been presented were not based on thorough analysis of independent ovarian cancer stem cell samples and therefore may not be consistently effective. In contrast, the treatments proposed by this analysis would likely target ovarian cancer stem cells across multiple subtypes.

While this project provides further understanding of ovarian cancer stem cells, additional research is necessary. Gene expression differences require validation via functional assays. These differences must also be confirmed in patient samples, ideally in a large cohort that includes all subtypes. Finally, proposed therapeutic

targets need to be tested for effectiveness against ovarian cancer stem cells. Should additional research confirm the results of this study, therapy targeting ovarian cancer stem cells may provide durable remission for patients.

Allison C Sharrow

Born February 15, 1982 in Pittsburgh, PA

Education

Doctor of Philosophy; Pathobiology February 2014

Johns Hopkins University School of Medicine Baltimore, MD

Dissertation: Identification and Characterization of a Stem Cell-Like

Population in Ovarian Cancer

Bachelor of Science; Molecular Biology, Biochemistry Track April 2004

University of Pittsburgh Pittsburgh, PA

Magna Cum Laude, Minor: Sociology

Research Experience

Johns Hopkins University School of Medicine October 2007 – Present

Graduate Researcher Baltimore, MD

Advisor: Richard J. Jones

- Develop research plan
- Characterize aldehyde dehydrogenase high ovarian cancer cells using cell sorting, flow cytometry, cell culture-based assays and molecular techniques
- Optimize culture and sorting conditions for ovarian cancer stem cells

University of Pittsburgh

April 2004 - July 2006

Research Associate

Pittsburgh, PA

Advisor: Harry C. Blair

- Examined regulation of osteoblast connectivity
- Isolated human osteoclast precursors to study effects of sex hormones on differentiation
- Supervised undergraduate research associates
- Managed lab supplies

University of Pittsburgh

April 2001 - April 2004

Undergraduate Research Associate

Pittsburgh, PA

Advisor: James M. Pipas

- Engineered expression vectors and purified overexpressed proteins to determine protein interactions
- Managed lab supplies

University of Pittsburgh

September 2000 - April 2001

Undergraduate Research Assistant

Pittsburgh, PA

Advisor: Tia-Lynn Ashman

- Managed *Fragaria* greenhouse colony
- Collected and analyzed specimens
- Entered data

Teaching Experience

Towson University

August 2010 - May 2011

Adjunct Professor, Biology: The Science of Life

Baltimore, MD

- Developed course syllabus
- Prepared and delivered lectures, facilitated class discussions
- Designed and graded assignments and exams
- Supervised laboratory sections

Johns Hopkins Bloomberg School of Public Health

August 2008 and 2009

Teaching Assistant, Introduction to Biomedical Sciences

Baltimore, MD

- Facilitated active learning exercises
- Prepared and delivered short lectures

University of Pittsburgh

Fall Semesters 2001-2003

Teaching Assistant, Freshman Studies

Pittsburgh, PA

- Assisted in course planning
- Prepared and delivered lectures
- Facilitated classroom discussions

Honors and Awards

Brackenridge Fellow

2002

University of Pittsburgh

Professional Memberships

American Society of Bone and Mineral Research	2005 - 2006
Western Pennsylvania Division March of Dimes Board of Directors	2004 - 2006
Team Youth Liaison	
Tri-Beta Honors Fraternity	2002 - 2004
Regular Member	
Western Pennsylvania Division March of Dimes Team Youth	2004 - 2006
Volunteer Advisor	
Team Youth Volunteer	1997 – 2004
Chair, Co-Chair and Secretary	

Peer-Reviewed Publications

1. Sharrow AC, Perkins BP, Yu W, Jones RJ. Identification and characterization of aldehyde dehydrogenase high ovarian cancer cells. In preparation.
2. Sharrow AC, Ronnett BM, Thoburn CJ, Barber JP, Giuntoli RL, Armstrong DK, Jones RJ, Hess AD. Identification and characterization of a spontaneous ovarian carcinoma in Lewis rats. J Ovarian Res. 2010 Mar 31; 3:9.
3. Robinson LJ, Tourkova I, Wang Y, Sharrow AC, Landau MS, Yaroslavskiy BB, Sun L, Zaidi M, Blair HC. FSH-receptor isoforms and FSH-dependent gene transcription in human monocytes and osteoclasts. Biochem Biophys Res Commun. 2010 Mar 26; 394(1): 12-17.

4. Sharrow AC, Li Y, Micsenyi A, Griswold RD, Wells A, Monga SS, Blair HC. Modulation of osteoblast gap junction connectivity by serum, TNFalpha, and TRAIL. *Exp Cell Res*. 2008 Jan 15; 314(2): 297-308.
5. Yaroslavskiy BB, Sharrow AC, Wells A, Robinson LJ, and Blair HC. Necessity of inositol (1,4,5)-trisphosphate receptor 1 and μ -calpain in NO-induced osteoclast motility. *J Cell Sci*. 2007 Aug 15; 120(16): 2884-2894.
6. Borysenko CW, Garcia-Palacios V, Griswold RD, Li Y, Iyer AK, Yaroslavskiy BB, Sharrow AC, Blair HC. Death receptor-3 mediates apoptosis in human osteoblasts under narrowly regulated conditions. *J Cell Physiol*. 2006 Dec; 209(3): 1021-8.
7. Sun L, Peng Y, Sharrow AC, Iqbal J, Zhang Z, Papachristou DJ, Zaidi S, Zhu LL, Yaroslavskiy BB, Zhou H, Zallone A, Sairam MR, Kumar TR, Bo W, Braun J, Cardoso-Landa L, Schaffler MB, Moonga BS, Blair HC, Zaidi M. FSH directly regulates bone mass. *Cell*. 2006 Apr 21; 125(2): 247-60.
8. Yaroslavskiy BB, Zhang Y, Kalla SE, Palacios VG, Sharrow AC, Li Y, Zaidi M, Wu C, Blair HC. NO-dependent osteoclast motility: reliance on cGMP-dependent protein kinase I and VASP. *J Cell Sci*. 2005 Dec 1; 118(23): 5479-87.

9. Frattini A, Blair HC, Sacco MG, Cerisoli F, Faggioli F, Cato EM, Pangrazio A, Musio A, Rucci F, Sobacchi C, Sharrow AC, Kalla SE, Bruzzone MG, Colombo R, Magli MC, Vezzoni P, Villa A. Rescue of ATPa3-deficient murine malignant osteopetrosis by hematopoietic stem cell transplantation in utero. Proc Natl Acad Sci U S A. 2005 Oct 11; 102(41): 14629-34.

Book Chapters

Sharrow AC, Ghiaur G, Gerber JM, Jones RJ. Cancer Stem Cell Principles. In Translational Cancer Research: Molecular Therapeutics. Wiley. In press.

Presentations and Posters

Fellow Research Day: Poster Presentation	May 14, 2013
Identification and Characterization of Aldehyde Dehydrogenase High Ovarian Cancer Cells	Baltimore, MD
Pathology Young Investigator's Day: Poster Presentation	April 5, 2013
Identification and Characterization of Aldehyde Dehydrogenase High Ovarian Cancer Cells	Baltimore, MD
American Society of Bone and Mineral Research Annual Meeting: Poster Presentation	
TRAIL and TNF α Regulate Human Osteocyte-Osteon	September 24, 2005
Structure by Removal of Gap Junctions via Proteasomal	Nashville, TN
Degradation with a Probable β -Catenin Downstream Mechanism	

March of Dimes National Team Youth Conference: Oral Presentation July 28, 2005

The Gene Pool: Research and the March of Dimes Washington, D.C.

University of Pittsburgh Medical School Pathology Retreat: Oral Presentation

Protein Kinase Activity and Death Receptor Ligands June 25, 2005

Modulate Osteoblast Connectivity Seven Springs, PA

Abstracts

1. Sun L, Zhang Z, Peng Y, Iqbal J, Zaidi S, Papachristou DJ, Zhou H, Sharrow AC, Yaroslavskiy BB, Zhu L, Zallone A, Sairam MR, Kumar TR, Cardoso-Landa L, Schaffler MB, Moonga BS, Blair HC, Zaidi M. FSH Directly Regulates Bone Mass: Implications for Understanding the Pathogenesis of Osteoporosis Due to Hypogonadism. *Journal of Bone and Mineral Research*. 2005; 20 (Supplement 1): Abstract #1043, pg S12.
2. Zhang Z, Sun L, Peng Y, Iqbal J, Zaidi S, Papachristou DJ, Zhou H, Sharrow AC, Yaroslavskiy BB, Zhu L, Zallone A, Sairam MR, Kumar TR, Cardoso-Landa L, Schaffler MB, Moonga BS, Blair HC, Zaidi M. The Pituitary Hormone, FSH, Directly Enhances Osteoclast Formation and Survival. *Journal of Bone and Mineral Research*. 2005; 20 (Supplement 1): Abstract #1100, pg S26.
3. Yaroslavskiy BB, Sharrow AC, Papachristou DJ, Virji M, Sun L, Zhang Z, Peng Y, Iqbal J, Zaidi S, Zhou H, Zhu LL, Moonga BS, Zaidi M, Blair HC. FSH as a Direct Regulator of Bone Degradation in the Human. *Journal of Bone and Mineral Research*. 2005; 20 (Supplement 1): Abstract #F376, pg S92.

4. Robinson LJ, Sharrow AC, Garcia Palacios V, Xue J, Blair HC. Nongenomic Estrogen Signalling Regulates Osteoclast Formation via An Adaptor Protein, BCAR1, that also Modifies Breast Cancer Progression. *Journal of Bone and Mineral Research*. 2005; 20 (Supplement 1): Abstract #F505, pg S103.
5. Sharrow AC, Li Y, Micsenyi A, Borysenko CW, Lehmann T, Wells A, Kalla SE, Garcia Palacios V, Monga SP, Blair HC. TRAIL and TNF α Regulate Human Osteocyte-Osteon Structure by Removal of Gap Junctions via Proteasomal Degradation with a Probable β -Catenin Downstream Mechanism. *Journal of Bone and Mineral Research*. 2005; 20 (Supplement 1): Abstract #SA217, pg S140.
6. Yaroslavskiy BB, Kalla SE, Sharrow AC, Blair HC. Guanylyl Cyclase and cGMP-Dependent Protein Kinase I Induce Calcium and Calpain-Dependent Cytoskeletal Rearrangement in Osteoclasts, but Calcium Signals Are not Sufficient to Initiate Motility. *Journal of Bone and Mineral Research*. 2005; 20 (Supplement 1): Abstract #SA241, pg S143.
